Things did not go so happily in E. Africa. Early in Aug. 1914 the German governor at Dar es Salaam had agreed to regard the ships there as British prizes, but when the boats of the "Goliath" and "Fox" entered the harbour on Nov. 28 1914, to disable them, a heavy fire was opened in total disregard of the governor's agreement. Comm. Peel Ritchie was severely wounded in bringing the boats out of harbour, and won a V.C. Far inland on Lake Tanganyika two motor-launches, the "Mimi" and "Tou-tou," arrived in Dec. 1915, and after an action with the German craft secured British communications there. They were under Comm. Spicer Simson, who brought them all the way from the Cape by land, a long journey of 2,000 miles. Early in 1916 another German ship managed to get out of the North Sea, and in March slipped into Sudi, a port in the south of the colony, bringing von Lettow Vorbeck, the German military commander, an invaluable cargo of munitions and stores, which enabled him to continue the campaign.

The coastline of German E. Africa remained in the enemy's hands till June 1916, when Tanga was occupied by the cruisers "Talbot" and "Severn." Bagamoyo was occupied by the old battleship "Vengeance" and the cruiser "Challenger" on Aug. 15 1916, and by the end of Sept. Rear-Admi. Edward Charlton, with his flag flying in the "Vengeance," could report the whole coastline in British hands. But in the interior fighting dragged on till the Armistice.

In Sept. 1918 there came news of the last German raider, the "Seeadler" (Capt. von Luckner), which left Bremen on

Dec. 21 1916, and slipped through the blockade line disguised as a Norwegian schooner laden with timber. Armed with 2 4-in. guns and manned by 68 men she had cruised off S. America and sunk six British ships ("Gladys Royle" Jan. 9, "Lundy Is." Jan. 10, "Perce" Jan. 28, "Pinmore" Feb. 19, "British Yeoman" Feb. 26, "Horngarth" March 11), and then rounding Cape Horn disappeared into the Pacific. There she anchored off Mopiha, a small atoll in the Society Is. 265 m. W. of Tahiti, but had dragged on to a reef and broken her back. The captain set off with five men in one of the ship's motor-boats for Cook Is., and was captured by a small British steamer. The rest of the crew captured a small French schooner, the "Lutece," calling at Mopiha for copra, and set off in it leaving their 48 prisoners to their fate, only to be wrecked on Easter I. and rescued by the Chilean schooner "Falcon." Capt. Smith, one of the prisoners, steered a leaky whaler from Mopiha to Tutuila in the Samoa Is., and a French schooner was sent from Papeete for the remainder. Out of six attempts by German raiders to pass the blockade, four were successful; their cruises were unstained by the incidents which marred the German submarine campaign, and might rank as the brightest exploits of the German navy during the war.

*Conclusion.*—The war was now drawing to a close. In July 1918 Adml. Scheer was summoned to Great Headquarters and on Aug. 11 took Adml. von Holtzendorff's place as chief-of-staff, von Hipper replacing him as commander-in-chief. In Sept. the hammer blows of Marshal Foch in France were beginning to tell, and on Sept. 18 Scheer was told to be ready to evacuate the Flanders coast. On Sept. 29 the Bulgarian front collapsed, and on Oct. 5 Germany was suing for peace. Soon immense explosions heraldcd the evacuation of the Belgian coast. On Oct. 17 their troops evacuated Ostend. Two days later they were in full retreat from Zeebrugge. Eleven destroyers and nine torpedo-boats succeeded in retiring safely to the Bight. The submarines left there were blown up. Scheer was anxious to continue the warfare against shipping to the bitter end, but on Oct. 21 the submarines received orders to cease the campaign and return home. He then set to work to prepare a great final sortie of the High Sea Fleet. The submarines were ordered on Oct. 22 to assemble off the Scottish coast. It was hoped to make a last great raid on the Channel while the submarines attacked the fleet on its way down. A large minefield had been laid outside the Forth to meet such a contingency, and Adml. Scheer included it unwittingly in his plan, not knowing that it had been swept up. But the plan was never to be fulfilled. Scheer saw the weapon he trusted break in his hands. On Oct. 29, when the signal was made to prepare for sea, a great clamour arose, and a mutiny broke out which reached such dimensions that Adml. von Hipper was compelled to abandon his project. The torpedo flotillas and submarines remained true, and the commodore of submarines was joined by 16 boats off Heligoland and on Nov. 8 took refuge in List. But the end was at hand. Revolution flamed up everywhere. The troops sent to quell the disturbance proved untrustworthy. The navy passed into other hands. The war was over.

Under the terms of the Armistice, 10 German battleships, 6 battle-cruisers, 8 light cruisers, 50 destroyers and all submarines were to be surrendered. On Friday, Nov. 15, Adml. Hugo von Meurer arrived in the "Königsberg" in the Forth to make the final arrangements with Adml. Beatty. On Wednesday, Nov. 20, the submarines began their sorrowful journey to Harwich, to be met by Rear-Adml. Sir Reginald Tyrwhitt 35 m. from the Essex coast. Their old enemies passed in to Harwich in dead silence. Not a sound was heard from the crowds watching them on shore or sea. On Nov. 21 the battleships of the proud German navy passed into Beatty's hands. It was a misty day, and the Grand Fleet stood waiting off the Forth in two long lines 6 m. apart. The light cruiser "Cardiff," flying Rear-Adml. Alexander Sinclair's flag, led the remains of Germany's navy up the lines.

The naval conditions of the Peace terms, signed in June 1919, comprised 17 articles and provided that the German navy was not to exceed 6 battleships of a pre-dreadnought type, 6 light cruisers, 12 destroyers and 12 torpedo-boats, and was not to include submarines. Within two months of signature the 8 dreadnoughts still in German possession ("Oldenburg," "Thüringen," "Ostfriesland," "Heligoland," "Posen," "Westfalen," "Rheinland," "Nassau"), 8 light cruisers, 42 modern destroyers and 50 modern torpedo-boats, were to be surrendered, disarmed but with all guns on board. At the expiration of one month all German submarines building were to be handed over; such as could proceed or be towed were to be taken to Allied ports indicated; the remainder were to be broken up. No warships were to be constructed or acquired other than those intended to replace the previously specified strength, and units were only to be replaced in the case of battleships at the end of 20 years, in the case of destroyers at the end of 15. The personnel, including reserves of the fleet and coast defences, was not to exceed 15,000 officers and men.

The disposal of the German ships gave rise to lively argument. Great Britain was in favour of destroying them. France wished to add her share to her fleet. The question was complicated by the scuttling of the ships at Scapa on June 21. There were interned there 11 battleships ("Baden," "Bayern," "Friedrich der Grosse," "Grosser Kurfürst," "Kaiser," "Kaiserin," "Kronprinz Wilhelm," "Markgraf," "Prinzregent Luitpold"), 5 battle-cruisers ("Hindenburg," "Derfflinger," "Seydlitz," "Moltke," and "Von der Tann"), 6 light cruisers ("Emden," "Frankfurt," "Nürnberg," "Cöln," "Dresden," "Karlsruhe," "Brummer" and "Bremse"); when at 11:15 A.M., on a signal from the "Emden," the ships were scuttled and began to sink. Only four were salved, the "Baden," "Emden," "Frankfurt" and "Nürnberg." Germany did not gain much by this act. She had to hand over in default of the battleships 400,000 tons (reduced later to 300,000) of floating docks, her remaining light cruisers ("Graudenz," "Königsberg," "Pillau," "Regensburg," "Strassburg"), to replace the light cruisers, and 42,000 tons of floating cranes, tugs and dredgers, instead of the destroyers; these were more useful than what was sunk.

The terms of peace were no mere formality. The destruction of the submarines and vessels building was entrusted to a naval section of the Inter-Allied Commission, under Vice-Adml. Sir Montague Browning (subsequently under Vice-Adml. Sir Edward Charlton), and was strictly executed. The fortifications of Heligoland were razed to the ground. The destruction of Germany's sea-power was complete. It had been achieved by economic pressure and the imminence of a great military defeat, engineered by the maritime power excited by a superior fleet. Strangled by sea-power, and with a vast military spearhead launched at her heart, Germany collapsed. The year 1920, which had been intended to see the fulfilment of her Navy Law of 1900 embodied in a fleet of 61 capital ships, 40 cruisers and 144 destroyers, saw the fabric of her naval aspirations shattered, her proud fleet sunk beneath the waves in a bleak harbour of the north, her Emperor, who had inspired its creation, a fugitive in a foreign land, and foreign admirals sitting in her capital superintending the destruction of its shattered remnants.

The fleets of the Allied and Associated Powers covered every sea, and their immense superiority is shown in the following figures:—

| | Dread-noughts. | Battle Cruisers. | Light Cruisers. | T.-B. Ds. | Sub-marines. |
|---|---|---|---|---|---|
| Allied and Associated Powers | 64 | 16 | 138 | 477 | 356 |
| Germany and Austria | 21 | 6 | 41 | 134 | 239 |

The Grand Fleet was now almost twice as numerous as when it had steamed N. on its fateful way in Aug. 1914. Its two destroyer flotillas had increased to eight, its single light-cruiser squadron had become six. It mustered, with Rear-Adml. Rodman's squadron, 38 battleships, making with Rear-Adml. T. S. Rogers' B.S. squadron at Berehaven ("Nevada," "Okla-

homa," "Utah") a total of 41 in British waters. It had 9 battle-cruisers and 39 cruisers and light cruisers, and attached to it were no less than 7 destroyer flotillas, mustering 167 destroyers (11th, Capt. Roger Rede; 12th, Capt. H. M. Leveson-Gower; 13th, Capt. Arthur B. S. Dutton; 14th, Capt. H. R. Godfrey; 15th, Capt. R. Rowley-Conwy; 3rd, Capt. Ed. Rutherford; 20th, Capt. Berwick Curtis, and 21st), and 5 submarine flotillas (10th, 11th, 12th, 13th, 14th) with 48 submarines.

The British losses had not been small. They amounted to 254 vessels, of which the greatest number had fallen to enemy submarines.

sea was kept open for the troops and trade of the Allies, and the shores of Great Britain and France were kept safe from invasion. Germany's path to the ocean was barred. It may be said that the path of German submarines was not barred, but German submarines merely attempted to do laboriously and slowly what a couple of German battle-cruisers appearing unopposed in the Channel could have done at once. And though the submarine was powerful against merchant shipping, it accomplished much less against the fleet. Not a single dreadnought was sunk by it during the war, and except in the narrow waters of the Adriatic no battle-fleet was ever kept in harbour by fear

Of auxiliary craft 815 had been sunk, including 246 trawlers, 244 colliers, 130 drifters, 44 oilers, 24 motor-launches and 18 minesweepers. Of the total 289 (35·4%) had been sunk by submarine, 225 (27·7%) by mine, and 77 (9·4%) had been wrecked. The losses of the other Allied navies were not so heavy in comparison.

[1] Approximate.

Though the figures give a very meagre picture of the colossal ramifications of the war, they leave ample room for comment. The submarine inflicted and suffered most of the damage done in the war. It was the most active and most dangerous service. In the North Sea Great Britain and the United States maintained a force of 46 capital ships (battleships and battle-cruisers) against the German 23, in numbers a twofold, in gun-power a threefold superiority. In the Mediterranean, France and Italy could muster 12 dreadnoughts against Austria's scanty three. What was the use of this immense superiority in battleships if it could not bring the German navy to action? The answer is that it represented the outlook of 1913, not of 1918. The French, Italian and U.S. dreadnoughts had been laid down before the war, and could not be converted into destroyers at a moment's notice.

The work wrought by sea-power, envisaged as a whole, was evident enough. German trade was swept off the sea. The

of submarines. The submarine, like the mine, must be regarded as an adjunct of the capital ship and not a substitute for it. It was countered by anti-submarine flotillas and convoys working under the aegis of the battle-fleet, which except in the case of the raids on Dover preserved them immune from attack. Again, the unrestricted use of the submarine involved the defiance of neutrals, an attitude which after the experience of this war few Powers will care to adopt. Each class of ship has its virtues, and naval strength cannot be expressed in terms of any single type. The various types are complementary to one another. The capital ship represents the highest synthesis of guns, protection and speed which the level of technical knowledge can supply. The submarine can attack the battle-cruiser, but the destroyer and aircraft can drive off the submarine, and the former can be driven off by the light cruiser, which in its turn can not approach the battle-cruiser.

The fact that there was no great decisive battle has made some doubt the further use of the battleship. It is true that the opportunity lost at Jutland was never wholly redeemed. The battle in war represents the economy of the decisive blow. Vast resources of personnel and material had to be kept locked up in the Grand Fleet, which a decisive battle would have released for the war against the submarine. The German fleet remained, too, something much more than a "fleet in being," for by guarding its minesweepers from attack it kept the Bight open for its submarines and took an active part in their campaign. The Grand Fleet still barred its way to the west but in conjunction with the minefield the German ships held the door of the Baltic and exercised an active command there. But though the capital ship still retains its place in naval war its particular design and its relative status leave large room for discussion. One may well ask why millions should be spent in giving it bulges to render it unsinkable. The "Moltke" was hit twice by torpedoes and did not sink. Again, do we not strain too much after the heaviest possible gun? The "Von der Tann" had 11-in. guns and the "Queen Mary" 13·5-in., but the former blew up the latter. These questions, however, belong rather to gunnery and tactics than to naval strategy.

The war left the world still on the horizon of other poten-

tialities. Submarines and aircraft never actually coöperated in a fleet action, though the value of the former in reconnaissance work was clearly demonstrated in the later stages of the war. In deep and narrow stretches of waters, however, it became almost supreme. Thus in the Adriatic the Austrian battleships dared not venture out and the Allied battleships dared not venture in. The power of the mine was one of the lessons of the war, and the combination of a minefield supported by the heavy guns of a fleet or by forts remained insurmountable to a fleet alone; the mines prevented ships approaching the fort or fleet, and the forts and fleet prevented minesweepers approaching the mines. This problem can only be solved by capturing the forts as the Germans did at Ösel in 1917, but even there three battleships were severely injured by mines. The mine must not be regarded as a purely defensive weapon. It can be and was very offensive, and at the Sound and Dardanelles was too strong for the stronger fleet.

Certain outstanding lessons remain from the war. Invasion becomes more hazardous than ever in the face of numerous and powerful aircraft, while aircraft carriers with opposing aircraft are necessarily enormous vessels and very vulnerable to attack. The truism that ships cannot engage forts was proved to be true. The power of the minefield was clearly demonstrated. Certain fallacies in evidence before the war received a severe shock. One of these used to be embodied in the expression that the sea is all one, but the war showed that the North Sea was one and the Baltic another. Maritime geography remains a dominating factor in naval war.

When the war broke out, grave doubts arose as to the advisability of sending a British army to France in the face of an undefeated German fleet. Maritime geography and the Dover Straits permitted this to be done in safety. The war was dominated by the fact that Germany's path to the ocean was barred by the solid bulk of Great Britain, and that both navies were working close to their main magazines of repair and supply. The full strength of all the combined weapons, air, sea and submarines, can only be exerted within a reasonable distance of one's own bases, and the navy fights with greatest advantage that fights in the vicinity of its great bases and industrial centres. Very different would be the conditions of a war 5,000 m. away. The development of aircraft, and the necessity of a host of auxiliary craft, tend to produce what may be called areas of maximum control for each power. Within its own area a navy tends to be supreme. The farther away it goes the heavier becomes its task. A war at a great distance would be waged under a heavy handicap, and would tend towards the conditions existent between Venice and England in the 15th century. They were too far apart to go to war.

It is barely possible for a single mind to envisage all the aspects of so colossal a war, or to gauge precisely the relative parts played in the victory by economic, naval and military pressure. But this at least may be said. If the British navy in 1914–8 had an even greater task to face than anyone dreamt of when King George had described it as the "Sure Shield" of its country at the outbreak of war, it could feel that this confidence had not been misplaced when the memorable day came for Beatty to receive the surrender of the German fleet under the Cross of St. George and the Stars and Stripes. (A. C. D.)

**NAVIES:** *see* SHIP AND SHIPBUILDING.

**NAVY, DEPARTMENT OF THE** (United States): *see* ADMIRALTY ADMINISTRATION (section *United States*).

**NEAL, DAVID DALHOFF** (1838–1915), American painter (*see* 19.320), died in Munich, Germany, May 2 1915.

**NEBRASKA** (*see* 19.323).—The pop. in 1920 was 1,296,372, an increase of 104,158, or 8·7%, over the 1,192,214 of 1910, as against an increase of 11·8% in the preceding decade. The foreign-born whites decreased from 176,662 in 1910 to 149,652 in 1920. The density of pop. was 16·9 per sq. m. as against 15·5 in 1910. The urban pop. (in places of 2,500 or more) was 405,306, or 31·3% of the whole, as against 310,852, or 26·1% of the whole, in 1910; the rural pop. was 891,066, or 68·7%, as against 881,362, or 73·9% in 1910.

The five cities having in 1920 a pop. over 10,000 were:—

| | 1920 | 1910 | Increase per cent |
|---|---|---|---|
| Omaha | 191,601 | 124,096 | 54·4 |
| Lincoln | 54,948 | 43,973 | 25·0 |
| Grand Island | 13,947 | 10,326 | 35·1 |
| Hastings | 11,647 | 9,338 | 24·7 |
| North Platte | 10,466 | 4,793 | 118·4 |

A conspicuous feature of the census returns was the continuing decrease of farming pop. in the older counties. Out of 93 counties 33 showed a decrease in total pop. and 43 showed a decrease in rural pop. during the decade. This rural decrease was in the part of the state where land sold at the highest price. The increase of pop. was almost entirely in three localities: Omaha, the chief industrial centre; Lincoln, the state capital; and the Scottsbluff irrigated region in the North Platte valley.

*Agriculture.*—In the decade 1910–20 farms tended to become fewer and larger, as shown by the following figures:—

| | 1920 | 1910 |
|---|---|---|
| Farms, total number | 124,417 | 129,678 |
| Total ac. in farms | 42,225,475 | 38,622,021 |
| Average size of farm (ac.) | 339·4 | 297·8 |
| Improved land | 23,109,624 | 24,382,577 |

The decrease in the number of farms was due to improved machinery (especially farm tractors), making the farming of larger units more economical, and to the higher price of land, making more difficult its purchase by persons of small means. The increase in size of farms was partly due to homesteads of 640 ac. taken in the sandhill part of the state under the Federal Kinkaid Homestead Act. All but a few thousand rough acres of the public domain in Nebraska had been claimed by settlers by 1921. In 1920 Nebraska ranked sixth among the states in area of cultivated lands. It was first in production of hay and of alfalfa; second in production of winter wheat; third in corn; third in combined production of wheat, oats and corn. About 1,000,000 ac. were in woodland, of which half or more had been planted by settlers.

Production of the principal crops for the years 1910 and 1920 is shown in the following table:—

| | 1920 | | 1910 | |
|---|---|---|---|---|
| | Ac. | Bus. | Ac. | Bus. |
| Corn | 7,560,355 | 255,544,816 | 6,505,088 | 178,925,128 |
| All wheat | 3,592,995 | 60,560,416 | 2,732,166 | 45,151,052 |
| Oats | 2,400,062 | 83,037,162 | 2,543,858 | 71,562,877 |
| Barley | 255,503 | 7,424,615 | 115,957 | 2,333,199 |
| Rye | 264,370 | 3,751,104 | 71,339 | 822,648 |
| Potatoes | 85,439 | 8,435,554 | 98,483 | 5,330,138 |

Great progress was made in the decade in production of alfalfa and sugar beets. The comparative figures are as follows:—

| | 1920 | | 1910 | |
|---|---|---|---|---|
| | Ac. | Tons | Ac. | Tons |
| Alfalfa | 1,232,947 | 3,527,689 | 701,455 | 1,883,661 |
| Sugar beets | 78,675 | 750,000 | 8,517 | 105,369 |

Growing potatoes on a commercial scale became a large industry in western Nebraska during the decade, about 8,000,000 bus. being produced annually.

The number of live stock on farms was:—

| | 1920 | 1910 |
|---|---|---|
| Horses | 961,396 | 971,279 |
| Mules | 99,847 | 79,652 |
| Cattle | 3,154,265 | 2,567,392 |
| Hogs | 3,435,690 | 3,435,724 |
| Sheep | 573,217 | 240,116 |

Farm tenantry increased during the decade as follows:—

| | 1920 | | 1910 | |
|---|---|---|---|---|
| Farms occupied by owners | 69,672 | 56 | 79,250 | 61·1 |
| Farms occupied by renters | 53,430 | 42·9 | 49,441 | 38·1 |

The percentage of tenants is greatest in the richer agricultural counties. About three-fourths of the tenants are renters for share rent. The landlord's share of grain crops is usually one-third of the small grain, two-fifths of corn, one-fourth of potatoes, one-fifth of sugar beets, one-half of the hay in stacks. In 1920 the total number of farm mortgages filed was 19,838 and their amount $116,440,626. The total number released was 17,514 and their amount $78,654,818. Most of these transactions arose from purchase and sale.

The Farmers' Coöperative and Educational Union became an organization of about 35,000 members in Nebraska during the decade. Its leading purpose is collective buying and selling. From it developed the Grain Growers, Inc., an organization covering all the states, with the purpose of handling the whole grain crop of the United States and securing better returns for the producer.

*Minerals.*—Of the pumice produced in the United States 97% is mined in Nebraska. Limestone, sand and Portland cement are increasing in production. Potash is found in alkali lakes in the sand-hill region of western Nebraska. The World War shut out importation from Germany, and commercial potash rose to 10 times its former price. The result was that a new industry sprang up; large amounts were invested, and over 2,000 men were employed. In 1918 Nebraska shipped about 150,000 tons of potash—three fourths of the total production in the United States. When importation from Europe was resumed the Nebraska production decreased and the future of the industry became uncertain.

*Industries.*—The progress of manufactures during 1909-19 is shown in the following table:—

Manufactures.

| | 1919 | 1914 | 1909 |
|---|---|---|---|
| Number of establishments | 2,884 | 2,492 | 2,500 |
| Wage-earners (average) | 36,521 | 25,144 | 24,336 |
| Capital | $245,256,684 | $121,007,944 | $ 99,901,089 |
| Salaries and wages | 61,808,692 | 24,010,977 | 19,438,719 |
| Value of products | 596,042,498 | 221,615,848 | 199,018,579 |
| Value added by manufacture | 115,268,376 | 47,502,164 | 47,937,608 |

Slaughtering and meat-packing, the chief manufacturing industry, in 1919 employed 10,122 wage-earners in 16 establishments and the products were valued at $303,849,000. Receipts of live stock at the Omaha stockyards indicate the growth of that industry in the past decade:—

| | 1919 | 1910 |
|---|---|---|
| Cattle | 1,874,996 | 1,223,533 |
| Hogs | 3,179,166 | 1,894,314 |
| Sheep | 3,789,188 | 2,984,870 |
| Horses and mules | 22,600 | 28,817 |
| Total | 8,865,950 | 6,131,534 |

*Banking and Finance.*—The Bank Guaranty law of 1909 and its amendment in 1911 provided for a fund from all state banks for protection of their depositors. The extraordinary growth of banking business which followed is shown in this table:—

| | 1919 | 1910 |
|---|---|---|
| Number of state banks | 999 | 666 |
| Number of national banks | 189 | 238 |
| Capital and surplus: state banks | $32,282,000 | $14,823,000 |
| Capital and surplus: national banks | 26,434,000 | 21,940,000 |
| Deposits: state banks | 270,050,000 | 70,454,000 |
| Deposits: national banks | 180,596,000 | 87,663,000 |

In 1919 Omaha ranked 13th among cities of the United States in respect of its volume of bank clearings, though 34th in population. The amount was in 1919 $3,058,973,348; in 1910 $832,971,607. The total legislative appropriations for the biennium 1909–11 were $6,248,362; for 1919–21 $15,963,392; for 1921–3 $26,513,771. The cash balance in the treasury Nov. 30 1920 was $2,089,631. There was no state debt. The total assessed value of the state (one-fifth actual value as prescribed by law) was in 1910 $412,138,607; in 1920 $775,949,730. The total state levies amounted to between six and seven mills on the dollar of assessed valuation. Under the new budget law of 1921 the date of the fiscal year was changed from April 1 to July 1. Heads of departments and institutions must make quarterly estimates in advance for expenditures of each quarter, which must be approved by the governor.

*Education.*—The total number of persons of school age in 1920 was 392,592; of these 311,821 were enrolled in school. The Nebraska law requires attendance of all children between 8 and 14 during 6 months of each year. There were 250,689 such children in the state, of whom 211,101 complied with this requirement. There were 7,168 school districts in the state. There were 12,705 women teachers and 1,084 men teachers. The total amount voted for school purposes in 1920 was $24,935,102. There were 100 consolidated school districts. The average monthly pay of men teachers was $134.42, of women teachers $86.26. The total value of school district property of all kinds was $142,145,280.

*History.*—The chief political issues in Nebraska during the period 1910–20 were prohibition, woman suffrage, initiative and referendum, reconstruction of the state Government and extension of public ownership. The first four issues were determined in the affirmative. The last mentioned was the subject of much controversy. The Democratic party carried the state in the elections of 1912, 1914 and 1916. The Republican party overwhelmingly carried the elections of 1918 and 1920. Party lines had been very much broken since 1900. Each of the leading parties developed a conservative wing and a progressive wing. The Non-Partisan League effected an organization in Nebraska. It was reported to have 25,000 members, but up to 1921 had succeeded in electing only a few of its candidates to office, its policy being to concentrate its votes in the primary of whichever party seemed to promise the greatest results.

A new political issue, that of language and religious instruction, arose out of the World War. About 200,000 Nebraskans were German-born or children of parents born in Germany. In many communities religious services and instruction were given in other languages than English. Through the efforts of the German-American Alliance, the Mockett law was enacted in 1913, providing for teaching the German language in the common schools upon petition of school patrons. The war caused antagonism toward everything connected with Germany. A general movement was inaugurated to drive foreign languages out of the schools and churches. The Mockett law was repealed. In its place was enacted the Siman law forbidding the use of any foreign language as a medium of instruction. The substance of this law was embodied in the state constitution Sept. 21 1920. The Legislature of 1921 amended the Siman law, making it more stringent. Out of more than 40 newspapers printed in foreign languages before the war, there remained only 10 in 1921.

Consolidation of some 20 state bureaus and organizations into 6 departments was enacted by the Legislature of 1919. A convention to revise the constitution met Dec. 5 1919. It submitted 41 amendments, all of which were adopted at a special election Sept. 21 1920. The most important were those providing for future amendment of the constitution by a majority of those voting on the question, provided such majority is 35% of total vote; providing for new executive offices by two-thirds vote of the Legislature; for classification of intangible property for taxing purposes; for the creation of a state industrial commission to administer laws relating to labour disputes and profiteering; making alien property rights wholly subject to the Legislature. The Legislature of 1919 provided a special tax and appropriated the proceeds to the amount of $5,000,000 for construction of a new state capitol. The erection of the building was entrusted to a State Capitol Commission.

The state furnished 49,614 men for service in the World War, of whom 3,021 lost their lives. To the Liberty and Victory loans and war charities Nebraska paid $264,760,000. Nebraska was first in *per capita* purchase of war savings stamps and her membership in the American Red Cross was 585,156—49% of the population.

The governors after 1910 were: Chester H. Aldrich (Rep.), 1911–3; John H. Morehead (Dem.), 1913–7; Keith Neville (Dem.), 1917–9; Samuel R. McKelvie (Rep.), 1919–21.

**NEGRO** (*see* 19.346*).—As a result of the publication of preliminary returns for the American census of 1920, it became possible in June 1921 not only to record the growth of the negro pop. of the United States during the decade 1910–20, but to compare the growth during 60 years of slavery with that during almost 60 years of freedom. In 1920 the negro pop. was 10,463,013, as compared with 9,827,763 in 1910, an increase of 635,250 or 6·5%. In the preceding decade the increase had been 993,769, or slightly over 11%. In the period between 1800 and 1860 the negro pop. increased from 1,002,037 to 4,441,830 or 343%; in the period between 1860 and 1920 it increased from 4,441,830 to 10,463,013 or 136%. The increase under freedom, although nearly twice as great numerically, was at only about four-tenths of the rate under slavery. Much of this difference is to be attributed to the negro's participation in the slackening rate of the country's growth. The white pop. of the United States, notwithstanding its reinforcement by more than 28,000,000 immigrants in the later period and only about 5,250,000 in the earlier, increased in the second 60-year period less than half as fast as between 1800 and 1860. The figures for the negroes show, however, that their emancipation has not stimulated the growth of population as emancipation of the Russian serfs did and as many Americans of a generation ago anticipated. During the

first period negroes increased about two-thirds as fast as whites; during the second little more than half as fast.

For a fuller examination of the changes in pop. growth, each of these 60-year periods has been divided into 3 of 20 years each, a method which neglects the admittedly inaccurate count of 1870 and the probably inaccurate count of 1890.

| | Increase of Negroes: Number | Per cent | Increase of Whites: Per cent | Per cent of Negro Increase to White (= 100) |
|---|---|---|---|---|
| 1800–20 | 769,619 | 76·8 | 82·7 | 93 |
| 1820–40 | 1,101,992 | 62·2 | 80·5 | 77 |
| 1840–60 | 1,568,182 | 54·6 | 89·7 | 61 |
| 1860–80 | 2,138,963 | 48·2 | 61·2 | 79 |
| 1880–1900 | 2,253,201 | 34·2 | 53·9 | 64 |
| 1900–20 | 1,629,019 | 18·4 | 41·9 | 44 |

The numerical increase rose period by period to a maximum in the last 20 years of the 19th century and then decreased, so that between 1900 and 1920 it was little more than it was 60 years before. The rate of increase, on the contrary, diminished steadily from period to period. At each period the rate of negro increase was less than that of the white. Apparently the immediate result of the Civil War and emancipation was to raise the relative rate of negro increase between 1860 and 1880 to nearly four-fifths of that of the white, a change due to the sharp check of white increase and a much slighter check in negro increase. But since 1880 the rate of negro increase has fallen much the more rapidly, and between 1900 and 1920 it was about four-ninths of that of the more numerous race. As a result of these changes negroes, who in 1800 were 18·9% of the country's pop., in 1920 were only 10%. If each race should increase through the present century at a rate identical with that prevailing between 1900 and 1920, as of course it will not, the pop. of the country in 2000 A.D. would be over 400,000,000, of which about 20,000,000, or one-twentieth, would be negro. The rate of increase of each race is likely to fall, but the difference in favour of the white race is unlikely to diminish.

The Census Bureau has compared the rates of increase of negroes and whites after correction for the probable inaccuracy of certain recent census figures. Those rates are reproduced below, with the addition of figures for 1920 and slight changes to allow for the fact that the intervals between the censuses of 1900, 1910 and 1920 were less than ten years.

| | Rate of Decennial Increase | | Per cent of Negro Increase to White |
|---|---|---|---|
| | Negroes | Whites | |
| 1860–70 | 21·4 | 27·5 | 78 |
| 1870–80 | 22·0 | 26·4 | 83 |
| 1880–90 | 17·6 | 26·7 | 66 |
| 1890–00 | 13·8 | 21·2 | 65 |
| 1900–10 | 11·4 | 22·3 | 51 |
| 1910–20 | 6·5 | 16·5 | 40 |

In the decade 1910–20 the percentage increase of negroes was two-fifths of that of the whites. Since 1880 the darker race has been relatively and rapidly losing ground.

In the years immediately following the Civil War a belief was commonly held that under freedom the negroes would rapidly distribute themselves over the country. At every census before 1870 between 91% and 93% of the negroes resided in the southern or slave states. Between 1860 and 1910 this proportion fell only from 92·2% to 89·0%. But between 1910 and 1920 it fell to 85·1%. During that decade the increase in the number of negroes living in the northern and western states was greater than the increase during the 30 years between 1880 and 1910. As a result of this outflow the negro pop. of the southern states increased only 2%, while that of the northern states increased 43% and of the western 55%. The movement cannot yet be thoroughly studied, but what information is available indicates that the migration has been almost exclusively to the northern and western industrial districts. Whether it is a temporary dislocation of population due to war-time conditions or a persistent drift cannot yet be foreseen.

The remarkable fall in the rate of negro increase and the rapid distribution of negroes over other parts of the country than the South are the striking changes revealed by the preliminary census figures. How is the fall in the rate of increase to be explained? Has it any connexion with the growth of interstate migration? To get light upon these questions we turn from the census figures of living population to the registration figures of births and deaths. Since 1900 the United States has been developing towards a national system of vital statistics by voluntary coöperation between the Federal Government and the Governments of the states and cities. For five years, 1915–9 inclusive, the births and deaths of negroes in a number of northern states, including the New England states, New York, Pennsylvania, Michigan and Minnesota, and for a shorter period the same facts for several other northern and a few southern states, are known.

The figures for the northern states are as follows:—

Births and Deaths of Negroes in Certain Northern States, 1915–9.

| | Births | Deaths | Natural Decrease | Deaths to 100 Births |
|---|---|---|---|---|
| New England | 8,634 | 9,101 | 467 | 105 |
| New York | 19,088 | 20,342 | 1,254 | 107 |
| Pennsylvania | 24,924 | 30,786 | 5,862 | 124 |
| Michigan | 2,971 | 3,488 | 517 | 117 |
| Minnesota | 525 | 870 | 345 | 166 |
| Totals | 56,142 | 64,587 | 8,445 | 115 (average) |

In each of these divisions negro deaths outnumbered negro births by an average of about 15%, and in consequence the increase of negroes in all these states, and probably in the other northern and western states, has been wholly due to immigration.

In the southern states the following compilation of all available figures shows results which are widely different:—

| | Years Covered | Births | Deaths | Natural Increase or Decrease | Negro Deaths to 100 Births | White Deaths to 100 Births |
|---|---|---|---|---|---|---|
| Maryland | 1916–9 | 25,418 | 25,407 | 11 | 100 | 68 |
| District of Columbia | 1915–9 | 11,042 | 13,280 | −2,238 | 120 | 81 |
| Virginia | 1917–9 | 57,244 | 42,971 | 14,273 | 75 | 48 |
| Kentucky | 1917–9 | 12,460 | 17,410 | −4,950 | 140 | 51 |
| North Carolina | 1917–9 | 67,724 | 42,633 | 25,091 | 63 | 41 |
| South Carolina | 1919 | 22,599 | 14,439 | 8,160 | 64 | 39 |
| Totals | | 196,487 | 156,140 | 40,347 | 79 | 52 |

While in each of the northern states for which the information exists negro deaths outnumber births, in the southern states the conditions are reversed: but to this rule there are exceptions. Kentucky and the District of Columbia resemble the North rather than the South. Maryland holds a middle position, births equalling deaths and the farther south the state the greater the excess of negro births over deaths.

The difference between the District of Columbia and the two states adjoining it suggests that an excess of deaths over births may be found in cities, whether northern or southern, rather than in northern states, whether mainly urban or not.

Births and Deaths of Negroes in Cities and Rural Districts of Registration Area, 1915–9.

| | Births | Deaths | Natural Increase or Decrease | Deaths to 100 Births |
|---|---|---|---|---|
| Cities | 100,203 | 121,306 | −21,103 | 121 |
| Rural districts | 169,353 | 122,565 | 46,788 | 72 |
| Total | 269,556 | 243,871 | 25,685 | 90 |

Clearly the difference between conditions in cities and those in rural districts is almost as influential upon race increase as the difference between South and North, which in this case closely parallels it. Further analysis shows that throughout the North and in the cities of the South deaths are more numerous than births.

| | Births | Deaths | Natural Increase or Decrease | Deaths to 100 Births |
|---|---|---|---|---|
| Northern cities | 58,921 | 68,698 | −8,777 | 115 |
| Northern rural districts | 14,148 | 19,033 | −4,885 | 135 |
| Southern cities | 41,282 | 52,608 | −11,326 | 127 |
| Southern rural districts | 155,205 | 103,532 | 51,673 | 67 |
| Total | 269,556 | 243,871 | 25,685 | 90 |

The figures show as conclusively as their incompleteness permits that the conditions under which negroes live in the North are unfavourable to the natural increase of their race and that in this regard no important difference appears between city and country. They show also that southern cities are even more unfavourable than those in the North to natural increase. The great reservoir for the natural increase of negroes is the rural districts of the South, in which apparently there are about three

births for every two deaths. This evidence seems to answer our questions. The sharp check in the growth of negro population between 1910 and 1920 was due primarily to the flood of migration from the agricultural districts of the South largely to the cities and industrial districts of the North, but partly also to the cities of the South, and the exposure of negroes in their new homes to conditions tending to raise the death-rate or reduce the birth-rate, or both. The census of 1920 showed that about 19·9% of the negroes were living in states other than those in which they were born. But contrary to popular belief the proportion of those who had migrated from the South to the North and West was only about one-fourth larger than that of those who had migrated from the North and West to the South.

The white race is not equally burdened. In the cities of the registration area in 1915–9 there were only 62 deaths among whites for each 100 births, the corresponding figure for negroes being 121. In this regard the negroes of the United States are in somewhat the same position as the whites on both sides of the Atlantic a century or more ago, when cities were in a sense parasites upon the surrounding rural districts, at whose expense alone they could grow or even maintain themselves.

(W. F. W.)

**NÉNOT, PAUL HENRI** (1853– ), French architect, was born in Paris in 1853, and when only 13 years old, was placed in the studio of M. Lequeux as architectural pupil, coming there under the influence of J. L. Pascal. Thence, when 15, he went to the École des Beaux-Arts, breaking off his studies in 1870, immediately on the outbreak of war with Germany, to enlist in an artillery regiment. Here he gained, as his first distinction, the Military Medal, and at the conclusion of the war, it was with difficulty that his patriotic enthusiasm allowed him to reassume a non-military life. He continued, however, his course at the École des Beaux-Arts, and in 1877 gained the Grand Prix de Rome. During these years he was working in the office of C. Garnier of the Opera House, Paris, and after the winning of the Grand Prix he travelled for a considerable time in Italy, Greece and Egypt. While holding this prize in Rome, he competed for the Victor Emmanuel monument in that city, receiving for his design the premium of 50,000 francs, the work itself being entrusted to an Italian. On his return to France, he entered for the great competition for the rebuilding of the Sorbonne, in which he was successful, and in 1882, despite discussion as to entrusting to so young a man such an important commission, he commenced in 1885 a work that was to occupy him for the next 17 years. He did not, however, undertake it till after a prolonged tour of inspection of the universities of Germany, Austria, Holland and Belgium. The building forms a huge parallelogram of over 900 ft. in length by 325 ft. in width, and its plan is brilliantly conceived, taking as its dictating condition the retention of Richelieu's chapel of the Sorbonne. Throughout the whole of his consideration of the treatment of this, as indeed of his other buildings, Nénot relied steadfastly on the assistance of the sculptor and the painter, and the grand amphitheatre gave him the opportunity he absolutely insisted on of employing for its decoration Puvis de Chavannes, whose mural painting of the "Sacred Grove" is his masterpiece. The hall itself, used as a *salle des conférences*, is an admirable example of the D-plan carried by a series of alcove recesses to an ultimate development. Nénot's other work gives evidence in equal manner of the tradition he carried forward from the school of which half a century before, Duc, Labrouste and Dubon were the founders and upholders, and shows a similar tendency to breathe fresh and revitalizing inspiration into the vernacular architecture of France. His other buildings, mostly in Paris, include the Institut Océanographique, the offices of the Compagnie Générale and those of the Compagnie Nationale des Wagons-Lits. He received many distinctions, becoming a member of the Institut in 1895, and being later elected president of the Société des Artistes Français. He was awarded the gold medal of the Royal Institute of British Architects in 1917.

**NERVOUS SYSTEM** (SURGERY).—The purpose of this article is to give a general view of the scope and limitations of surgery as applied to injury and disease of the nervous system. It is essentially concerned therefore with the principles of modern surgical neurology rather than with clinical, pathological or technical details.

The nervous system (*see* 19.400) is unique among the various systems into which the body is conventionally divided by the descriptive anatomist in being everywhere sharply marked off by definite anatomical and physiological boundaries from all the other tissues. It is a system in the strictest sense of the term. Its substance is elaborately insulated from contact with non-neural tissues except at the minutely limited points where contact is necessary for function, and correspondingly its pathology comprises principles which are characteristic and peculiar to it. In the mechanisms of injury or disease, in the processes of recovery and repair and in the response to the action of drugs the nervous system displays qualities which are special to it and not to be found elsewhere. It is natural therefore that the general principles of surgery need to be qualified in certain ways before they can be applied satisfactorily to surgical neurology.

The three great divisions of the nervous system—brain, spinal cord and peripheral nerves—coincide nearly enough with differences of surgical principle to allow the surgery of them to be dealt with under corresponding heads.

*Surgery of the Brain:*—The brain differs from all other organs of the body in being enclosed in a capsule of bone, and in a capsule therefore which is incapable of being stretched by any physiological force. The normal response of other organs to injury or disease is swelling, and this possibility of the occurrence of swelling allows of the presence of inflammatory products, of extravasated blood or oedema fluid without the circulation of blood through the organ being grossly impeded. In the case of the brain swelling the result of injury or disease is strictly limited by the skull, with the result that products of inflammation (or extravasated blood) or oedema fluid press on the vessels of the brain—veins, venules and capillaries according to the amount of exudation—and limit the circulation through them. The consequence is that any intracranial lesion other than a purely degenerative one is always accompanied by more or less wide-spread circulatory disturbances in the brain.

Now the functional activity of the brain is immediately dependent on blood supply, so that a cerebral lesion, as it necessarily interferes with blood supply, must always produce disturbances of function by this mechanism. In the case therefore of a given lesion such as a tumour or a haemorrhage the symptoms will be produced in two ways. First there will be symptoms due to loss of the function of the piece of brain occupied and destroyed by the tumor or haemorrhage, and secondly there will be symptoms due to disturbance of function in the surrounding region of brain where the circulation is impeded by pressure.

This dual causation of symptoms is a fundamental principle in cerebral pathology, and there are two corollaries of it of equal importance. In the first place the loss of function due to circulatory disturbance may be and frequently is as complete as if it were due to actual destruction of the brain substance; and in the second place the symptoms due to circulatory disturbance are in the majority of cases more conspicuous and more important than those due to the directly destructive effect of the lesion. It follows from these considerations that in many cases in which surgery is unable to deal curatively with the actual diseases itself it can produce benefit by dealing with secondary circulatory disturbance through the relief of pressure. Since the secondary pressure effects of many cerebral tumours are extremely distressing (severe headache, persistent vomiting and failure of vision), the merely palliative relief of abnormal intracranial tension is an important function of cerebral surgery.

While disturbance of function due to circulatory embarrassment can be got rid of if the abnormal intracranial tension can be completely relieved, loss of function due to destruction of the brain substance is permanent. There is no such thing as regeneration of the brain tissue, or the taking over of the actual function of a destroyed part by another part, and surgery can do nothing to restore a piece of brain that has been destroyed.

Having defined the general limitations within which the surgeon works in dealing with injury or disease of the brain we may next indicate in a summary way the chief procedures he is called upon to undertake.

*Curative Operations.*—By this term is meant procedures which are intended to do away with the primary cause of the symptoms in a given case, but it is of course to be understood that any element in the symptoms that may be due to destruction of brain tissue is necessarily irremediable.

(*a*) *Operations Curative by Relief of Intracranial Tension.*—When the brain has been severely bruised either locally or diffusely—a common result of head injury in civil and military practice—the subsidence of the contusion is very slow, and may be indefinitely delayed owing to the effects of the rigid encapsulation by the skull. In these circumstances the patient is apt to suffer for many months or even years from severe and disabling symptoms of which the most conspicuous is headache. Such symptoms can be arrested by the making of an opening in the skull and dura mater, which allows the brain to expand and the contusion to subside. Apart from injury certain cases occur in which increased intracranial tension develops in a way that suggests the existence of a cerebral tumour. An operation, however, discloses no tumour but a great increase of pressure, which subsides after an opening is made in the skull.

In these two types of cases the mere relief of tension is curative and when the opening in the skull has done its work it can be closed by a plastic operation.

(*b*) *Operations for the Removal of Extravasated Blood.*—When as the result of injury a large collection of blood forms on the surface of the brain, death necessarily follows unless the blood clot is removed by operation. If the blood remains fairly localised and the diagnosis is made early, treatment by operation is often brilliantly successful. Haemorrhage into the brain not due to injury—apoplexy—can occasionally be evacuated by operation with success. Unless, however, the patient is relatively young and otherwise healthy the prospect of success in a given case is very small. Most of the symptoms of haemorrhage of all kinds are due to secondary circulatory disturbance, but in so far as they are due to destructive disorganization they are beyond remedy, so that while a successful operation for apoplexy may save a patient's life it may leave him permanently paralyzed.

(*c*) *Operations for Abscess of the Brain.*—Abscess in the brain is due to the entry of pus-forming micro-organisms as the result of injury such as bullet wound, to extension from an infective focus near the skull such as inflammations of the ear and nose, or to micro-organisms reaching the brain through the blood stream from an infective focus elsewhere in the body, especially in the chest. In the two types first named the evacuation of the abscess according to the general principles of surgery is frequently successful; in the third type evacuation usually fails, because there are multiple abscesses or because the patient is too enfeebled.

(*d*) *Operations for Tumour of the Brain.*—Intracranial tumours are of three principal types of structure according to the situations in which they arise—tumours of the brain substance are gliomas, tumours of the membranes of the brain are endotheliomas, and tumours of the cranial nerves are neuro-fibromas. The *glioma* grows in the brain substance which it usually infiltrates; sometimes it is partially differentiated from the surrounding brain by an imperfectly formed capsule. If it is to be removed with any prospect of freedom from recurrence it must be taken out with a margin of apparently healthy tissue about it. Thus in extirpating a glioma a considerable amount of gross and irrecoverable damage is as a rule necessarily inflicted on the brain. It is in fact rarely the case that the prospect even then of securing permanent freedom from recurrence is good enough to justify the disability that the operation of itself is likely to cause. *Endothelioma* of the membranes does not infiltrate the brain substance, and can therefore be removed without the necessary infliction of any serious damage to the brain. When in an accessible situation and recognized fairly early it is the tumour which offers the best chance of cure with the least risk. *Neuro-fibroma* is almost confined to one situation, the auditory nerve in its course between the brain and the temporal bone of the skull. It thus lies in close relation to the cerebellum, is usually associated with cerebellar symptoms, and being separated from the surface of the skull by the lateral lobe of the cerebellum is in an extremely inaccessible situation. The tumour in itself is benign and slow growing, and owes its seriousness solely to the great technical difficulties of the operation to remove it. In favourable circumstances, however, the operation may be satisfactory.

These three representative neoplasms if untreated necessarily cause death; the only curative treatment of them is operative removal; the surgery of them while always difficult and frequently discouraging yields a sufficient number of wholly successful results to make application of it imperative in every case. At the present time the greatest obstacle to success is the difficulty of early and precise diagnosis. The dangers and difficulties of operations are greatly increased by the onset—sooner or later inevitable—of a severe and widespread increase of intracranial tension. Unfortunately it is often only on the evidence of this complication that a diagnosis is now made. Two lines of investigation are being pursued to-day which offer some hope of greatly improved diagnosis in cases of cerebral tumour. These are the radiographic examination of the ventricles of the brain after air has been injected into these cavities, and the artificial and temporary intensification of states of cerebral disturbance so that latent symptoms become manifest.

*Palliative Operations.*—In a large proportion of cases of cerebral tumour the surgeon is unable to carry out a radical operation. This may be because the tumour cannot be found, because its situation is inaccessible, or because the attempt at removal would involve too serious a risk or too serious a mutilation. In such cases, however, it may be possible to give great and prolonged relief of symptoms by an operation directed solely to the reduction of intracranial tension. This is the operation known as cerebral decompression. It has already been pointed out that the pressure effects of a cerebral tumour on the circulation in the adjacent brain substance are usually the source of its most distressing symptoms. These secondary circulatory symptoms are due to the rigidity of the skull, and can therefore be relieved by the making of an adequate opening in it. In favourable cases the relief given is immediate and very great, especially in regard to headache and vomiting and to the ocular changes (optic neuritis), which if allowed to progress cause blindness. The completeness and duration of such relief depend on the rapidity of the growth of the tumour and on its situation. It occasionally happens, moreover, that the rate of growth of a glioma seems to be checked indefinitely by the operation.

When the situation of the tumour is known the decompressive operation should always be made directly over it; when unknown, the opening is best made in the temporal region on the right.

The opening in the skull should be of an area not less than four or five sq. in., and the dura mater exposed in it should be freely incised. The effect of the operation is due to the brain expanding freely into the opening and forming a swelling under the skin.

The relief of suffering and the prolongation of life that may with reasonable confidence be expected from a decompressive operation are such that the operation should always be used in cases where the removal of the tumour is not possible.

*Plastic Operations.*—The function of the skull is not only that of protection but also that of support, so that after any considerable opening has been made in it the brain, if the intracranial tension has become normal, tends to become depressed, and also to undergo a good deal of movement with changes of bodily posture. Thus it comes about that the mere presence of an opening in the skull may be the cause of symptoms, and it may be necessary that the opening should be closed. This should never be done unless it is certain that the intracranial tension is normal, so that the operation is practically limited to cases in which the opening has been made for the treatment of the results of injury. The actual closure is effected by embedding some foreign material in the gap or by the use of flat bone grafts.

*Surgery of the Spinal Cord.*—To avoid unnecessary detail the spinal cord may be regarded simply as the great channel of communication between the brain and the rest of the body, and the problems of spinal surgery as concerned with the way in which interruptions of conductivity through this channel can be influenced by surgical measures. Interference with conductivity at a given level will produce a corresponding impairment of function in all the parts of the body connected with the spinal cord below that level, while a complete interruption of conductivity will cause a complete voluntary paralysis and insensibility in the same parts.

The spinal cord is enclosed in a strongly walled tube—the spinal canal—lying in the spinal column and mostly made up of bone. Its seclusion within the spinal canal protects the cord very thoroughly against all ordinary violence. At the same time, however, since the size of the cord is not very much less than that of the canal, any injury whereby the walls of the latter are broken or displaced, or any abnormal substance growing within it, can scarcely fail to impinge upon the cord and damage it. These then are the two sources of impaired conductivity which come before the surgeon—injury of the spine and intraspinal swellings in the nature of tumours or inflammatory deposits.

With regard to the resources of spinal surgery it is essential that it should be understood that there is no process of regeneration in the spinal cord; any destructive damage is permanent and incapable of remedy, so that if for example a part or the whole thickness of the cord is cut across conduction is finally interrupted at the divided place, and no suturing or grafting operation can restore it. Wherein, then, it may be asked, is the field of usefulness of the surgeon? The answer lies in the fact that conduction is frequently interrupted by pressure on the spinal cord without destruction of its substance, and in so far as an interruption is due to pressure only and has not been in existence long enough to produce secondary destructive effects it can usually be relieved and unction restored by operation.

*Spinal Injuries.*—When an injury is severe enough to break the wall of the spinal canal (falls, severe blows on the back, bullet or shell wounds), the total body of spinal cord symptoms is made up of three factors. First, shock to the cord which may abolish its functions, though there may be no corresponding gross and visible injury; this shock effect tends to pass off within a period extending to three or four weeks. Secondly, destructive injury of the cord by crushing or laceration, which in so far as it is destructive is permanent. Thirdly, interference with the cord by compression; the cord may thus be pressed on by a foreign body (bullet or shell fragment), by displaced bone of the spine, by swelling of the soft tissues (including the cord itself), from bruising, and at a later period by the results of scar formation in the injured tissues.

The surgeon has to take these three factors into account before undertaking an operation for spinal injury, and he must always remember that it is the third alone that he has any power favourably to influence. He will, therefore, necessarily wait until the shock element has passed off, and will determine this by the reappearance of reflex activity in the cord. He will then have to decide whether the probabilities are in favour of any considerable proportion of the symptoms being due to compression rather than to destruction of the cord. The difficulty is that there is nothing in the actual symptoms themselves to decide this, but experience shows that when very gross interruption of conductivity remains complete after the shock effect has passed off the proportion of symptoms due to the factor of compression is likely to be very small. The most hopeful field in the surgery of spinal injuries lies therefore where interruption of conductivity is manifestly incomplete.

*Spinal Tumours and Inflammatory Swellings.*—These conditions interrupt conduction in the spinal cord by slowly developing compression, so that there is nothing in the actual state of the cord inconsistent with recovery provided the compression has not lasted too long. Complete recovery may follow the removal of a compression that has caused total interruption of conduction for several months. When the compression has lasted very long incomplete recovery is the rule. The actual lesions that may occur are as follows: (1) Malignant tumours of the bones of the spine, primary or secondary, and much the more commonly the latter. Radical removal of the tumour is impossible, and operation for the relief of the pressure it is exercising on the cord is justifiable only in very exceptional cases. (2) Benign tumours of the spinal bones (osteoma, chondroma), of the spinal membranes (endothelioma, ammoma, fibroma), of the spinal vessels (angeioma), of the nerves (neuro-fibroma), and of the substance of the cord itself. Radical removal of the tumour can be carried out in most cases of this class. In early cases when the operation is successful complete recovery is the rule, and the results are brilliantly satisfactory. Spinal angeioma and tumours of the cord substance are not usually removable. (3) Inflammatory swellings. Chronic localized meningitis (meningitis circumscripta serosa) produces a loculated collection of fluid in the arachnoid membrane and causes pressure on the cord in much the same manner as a benign tumour. The results of operative treatment are usually satisfactory. Tuberculosis of the spine by extension of the granuloma or of an abscess into the spinal canal frequently causes compression of the cord. If the condition persists in spite of adequate treatment of the primary disease operation may be necessary to relieve the pressure on the cord.

The application of surgery to the relief of compression of the spinal cord by disease is on the whole, then, very satisfactory. When secondary malignant disease of the spine has been shown not to be present, the surgeon is able to enter upon an operation for compression paraplegia with the practical certainty of being able to give relief and the fair probability of attaining a cure.

*Surgery of the Peripheral Nerves.*—This department of surgery is almost wholly concerned with the repair of nerves which have been injured, and the relief of certain diseased conditions of which the principal symptom is pain. Outside of these two fields of activity the occasions on which surgery has to deal with the peripheral nerves are not many. There is only one common tumour of nerves and that is the neuro-fibroma. When this occurs on the auditory nerve within the skull or on a spinal nerve within the spinal canal its situation gives it an importance it does not in itself possess, which has already been referred to. Occurring elsewhere it is important only if it causes pain or tenderness, when it should be removed by operation.

*Treatment of Nerve Injuries.*—It is only in the peripheral nerves that the nervous system possesses the power of regenerating after destructive injuries. The common form of such injury is the division of a nerve by an accidental wound or a wound of war. After such a division the essential part of the nerve beyond the seat of the injury disappears, leaving only the framework of protective and supporting tissue by which it had been surrounded. After such a divided nerve has been stitched together a new growth of nerve fibres pushes out from the original cut surface downwards into the surviving old framework, and ultimately reëstablishes the functions that have been lost. This process of regeneration is by no means always fully accomplished even in favourable circumstances, and is very easily interfered with if the conditions are at all unfavourable. Favourable circumstances are that the divided ends should be sutured together early and with the proper operative technique, that the wound remain free from infection, and that the affected limb be kept in a state favourable for the resumption of its temporarily lost functions. Any deviation from these conditions greatly increases the normal uncertainties of the regenerative process. No limit, however, can be set to the time within which suture must be carried out in order to give some hope of effective regeneration. When so much of the length of a nerve has been destroyed that the ends cannot be brought together by any device short of a grafting operation, the chances of a satisfactory return of function are much reduced. In certain cases when recovery after nerve suture has failed to occur, or is extremely improbable, a limb satisfactorily useful from the motor point of view can be obtained by redistributing such motor power as remains by an operation of tendon transplantation. The maintenance of a healthy condition in the affected limb during the abeyance of function is an essential part of the treatment. The neglect of this aspect of the case may deprive a technically satisfactory operation of nerve suture of ultimate success.

*The Treatment of Neuralgia.*—The term neuralgia is used here to indicate the rather indefinite group of conditions in which pain is the sole or the wholly predominant symptom. To bring a given case within this group it must be shown that the cause of the pain does not lie outside the affected nerve. Only when this requirement has been satisfied can the appropriate surgical measures directed to the nerve be justifiably undertaken. This precision of diagnosis is indispensable, because the treatment to be used consists in the destruction by one means or another of the affected nerve, and it is plain that such a procedure would leave unaffected any condition of disease outside the nerve.

Injuries of nerves are a fruitful source of persistent pain of the neuralgic type under consideration. Any injury of a nerve is a potential starting point for neuralgia, but the division of nerves in an amputation is perhaps the commonest, especially in cases where the wound has become infected. Of neuralgias not associated with injury the dreaded trigeminal or trifacial neuralgia (tic douloureux) is the most frequent and most formidable. In both conditions three types of surgical procedure are in use—the removal of the terminal and affected part of the nerve, the injection of alcohol into the nerve above the affected part, or the division of the nerve close to its origin from the spinal cord or brain. The last-mentioned type of operation is not usually effective in the treatment of pain due to nerve injury, but it is curative in trigeminal neuralgia, and in spite of its gravity has in suitable circumstances to be undertaken.

(W. T.)

**NETHERLANDS INDIA** (*see* 17.466; 15.284; 26.70; 4.256; 5.596).—Netherlands India is divided into territories under direct (Dutch) rule and under native self-government subject to Dutch regulation. As regards the self-governed territories, the elaborate individual agreements originally made between the Dutch and native princes have in recent years been replaced in large measure by a form of political contract known as the "short declaration," which has helped to simplify relations between the parties. In the Outer Possessions or Outposts (*i.e.* the islands other than Java and Madura) there were in 1919 about 280 territories self-governed under the short declaration and only 19 under more detailed contracts; in Java (Surakarta and Jokyakarta) four native principalities remain, with little power. To the Dutch colonial system of government there has been recently added a people's council (Volksraad) of at least 39 members, including a chairman appointed by the Crown, five native and 14 European and foreign oriental members appointed by the governor-general, and 10 native and five other members elected by local councils. This body opened its first session on May 18 1918. The governor must consult it on the budget and certain other financial questions, on any question of general military serv-

ice, and on any other matters indicated by general Crown ordinance; and he may invite its opinion on other topics. The Dutch home Legislature, however, remains supreme in regard to financial, as to other colonial questions. The governor has now, in connexion with his executive functions, an advisory council consisting of the nine heads of administrative departments.

Netherlands India was in 1921 divided, for purposes of administration, into 35 provinces comprising three governments, 33 residencies, and one independent sub-residency. These are:—

In Java and Madura: Bantam, Batavia, the Preanger regencies, Cheribon, Pekalongan, Semarang, Rembang, Surabaya, Pasuruan, Besuki, Banyumas, Kudu, Jokya, Solo, Madiun, Kediri, Madura.

In Sumatra: Sumatra West Coast, Tapanuli, Benkulen, Lampong, Palembang, Jambi, Sumatra East Coast, Acheh (Achin) and dependencies.

Others: Riouw and deps., Banka and deps., Billiton, Borneo West Coast, Borneo South and East Coasts, Menado (in Celebes), Celebes and deps., Amboina and deps., Ternate and deps., Timor and deps., Bali and Lombok.

The native powers of administration, so far as capable of development, are carefully fostered by the Dutch. In 1918 an ordinance permitted various duties, in provinces determined by the governor-general, to be delegated by the provincial governors to native officials: this practice, started in part of the Preanger regencies, is in process of extension elsewhere in Java, but not, as yet, outside it. The Government maintains certain Chinese and Arab officials to advise it on administrative matters connected with the foreign oriental element in the population. In 1914 a civil service college was established at Batavia for the training of natives as well as foreigners in administration, and in 1918 a course of training for natives as civil servants was established in the S. of Sumatra.

*Population.*—The pop. of the principal islands or divisions of Netherlands India was given for the year 1917 (Dec.) unless otherwise stated:—

| | Native. | Foreign Oriental. | European. | Total. |
|---|---|---|---|---|
| Java & Madura. | 33,652,230 | 393,723 | 111,430 | 34,157,383 |
| Sumatra . . | 4,816,243 | 196,019 | 14,791 | 5,027,053 |
| Riouw & dependencies . . | 177,602 | 21,628 | 419 | 199,649 |
| Banka & dep. . | 81,923 | 71,714 | 541 | 154,178 |
| Billiton . . | 38,351 | 20,762 | 368 | 59,481 |
| Borneo . . | 1,427,021 | 83,634 | 2,448 | 1,513,103 |
| Celebes & dep. (inclu. Menado). . . | 3,081,758 | 28,093 | 4,223 | 3,114,074 |
| Amboina & dep. (1912) . | 354,754 | 2,999 | 3,181 | 360,934 |
| Ternate & dep. . | 198,465 | 1,193 | 477 | 200,135 |
| Timor & dep. . | 1,085,875 | 4,821 | 653 | 1,091,349 |
| Bali & Lombok . | 1,336,485 | 8,081 | 314 | 1,344,880 |

Amboina in the above table includes southern and western New Guinea, and Ternate includes northern New Guinea. The total pop. for the Outer Possessions was given as 12,579,897 natives, 438,944 foreign orientals, and 27,451 Europeans, and the percentage rate of increase since the census of 1905 is as follows:—

| | Natives. | Foreign Orientals. | Europeans. | All. |
|---|---|---|---|---|
| Java & Madura | 13·2 | 24·1 | 71·5 | 13·5 |
| Outer Possessions . . | 72·1 | 37·6 | 69·9 | 70·4 |

It is clear, however, that the apparently large rate of increase in the native pop. of the Outer Possessions is to be attributed in part to more effective measures of enumeration at the later census.

Recent census figures for certain large towns are:—Batavia(1917), 231,464; Surabaya (1918), 160,801; Surakarta (1918), 139,882; Semarang (1918), 106,852; Jokyakarta (1918), 97,058; Bandung (1918), 58,649.

It is no longer correct to regard Netherlands India as a "colony of officials," as it has sometimes been termed; there were in 1917 less than 9,000 Europeans in official positions, and the majority of the total European pop. were traders, tenants of plantations, officers of mining companies, and the like. Probably over nine-tenths were Dutch, though Germans appeared to have increased in numbers during the World War, finding the colony a convenient refuge and, it is said, a centre for intrigue against India and elsewhere. A few hundred British and Belgians were the other most important elements in the European population. Among foreign orientals Chinese were far the most numerous, numbering about 895,000 in Java, and 385,000 in the Outer Possessions; Arabs numbered about 19,000 and 10,000 respectively, and Hindus 24,000, mainly in the Outer Possessions.

*Religion and Instruction.*—Some 35,000,000 of the population were professedly Mohammedans, though not necessarily strict followers of Islam. The pilgrimage to Mecca was made in 1913 by 17,655 persons from Java, 5,318 from Sumatra, 1,485 from Borneo, and 629 from Celebes. In 1914 Christianity was represented among the natives by about 660,000 Protestants and 52,000 Roman Catholics; the Dutch Protestant Church had 41 pastors, with assistants. Protestant missionary bodies were united in representation by a consul at Batavia, who acts on their behalf in relations with the Government. They had 349 missionaries in 1915. The Protestant missions were mainly Dutch and German. Both they and the Roman Catholic missions succeed chiefly in the Outer Possessions where Islam is less powerful than in Java; notably in Celebes, Amboina and the Moluccas generally, Timor and New Guinea.

Education was systematically, if slowly, extended among the natives. Broadly speaking Government schools and native schools under Government supervision greatly outnumbered private schools in Java, whereas the contrary was the case in the Outer Possessions, where the missions (whose schools are reckoned as private) do most of their work There were 15 secondary schools in Java, including the *Hoogere Burgerscholen* at Batavia, Surabaya, and Semarang. A school for the training of native orators was opened in 1913, and a second school of agriculture in 1917. Other establishments included a school for native female teachers in Java (1918), and a new class of elementary trade schools (the former craft schools having left the native handicrafts almost unaffected), opened at several points in Java in 1915 and subsequently. The foundation of a technical university, primarily for civil engineers, was in hand.

The total State expenditure on education was estimated in 1920 at 20 million guilders (7½ millions on European and 12½ millions on native education). The following figures are for the year 1917:—European primary schools, 198; pupils 26,817 (including 5,852 natives and foreign orientals); Dutch-Chinese schools, 31; pupils 6,717; advanced primary schools, 14; pupils 1,615; private primary schools, 50 (34 State-subsidized); pupils 8,141. Dutch native schools, 115; pupils 21,690; native schools (2nd class), 989 in Java, 490 in Outer Possessions; 142,415 and 72,875 pupils respectively; native ("peoples' ") schools, 4,185 in Java, 1,372 in Outer Possessions; 299,516 and 83,127 pupils respectively; 14 special schools for natives, 3,132 pupils; 2,506 private schools for natives (145,505 pupils); 220 for Chinese (12,636 pupils), 32 for Arabs (1,928 pupils). Native law school, 65 pupils; native civil service training schools, 922 pupils; training schools for native teachers, 735 pupils; native trade schools, 316 pupils.

*Justice.*—While the distribution is maintained, as concerns the administration of justice, between (1) Europeans and persons "assimilated" with them, and (2) natives, Chinese, Arabs, etc., there is a general tendency to unify the civil code as the criminal code was already unified, and thus to bring such sections of the pop. as the Chinese under the same code as Europeans; as concerns natives, and foreign orientals in regard to their family law, the *adat* (native law) is respected so far as compatible with European standards. A general civil code was in preparation in 1921, with the object of admitting differences in legal practice only so far as the customs of various creeds and different native social views render them imperative. For Europeans there were in 1921 three courts of justice in Java, two in Sumatra, and one in Celebes. The *landgerecht* is the court for minor criminal offences among all sections of the pop. in Java and Madura, and these courts were in 1921 to be extended to the Outer Possessions (*e.g.* Macassar and Eastern Sumatra), where the residency courts act in the case of Europeans, and magistrates' courts in that of natives. A similar system of unification was in preparation as regards minor civil cases.

*Finance.*—Revenue and expenditure is shown thus for recent years (in thousands of guilders):—

| Year. | Revenue. | Expenditure. |
|---|---|---|
| 1910 | 221,516 | 231,427 |
| 1915 | 309,734 | 347,887 |
| 1916 | 342,968 | 373,199 |
| 1917 | 360,759 | 419,275 |
| 1918 | 384,694 | 490,859 |

The deficits were covered by loans raised in each year 1915–9 in the name of, and chargeable upon, the colony (previous loans having been contracted by the mother-country), amounting to 372,500,000 guilders. The deficits were due not merely to indirect results of the World War, but to the extension of Dutch rule in the Outer Possessions, improvements in the administration of law, education, and public health, promotion of industries, and extension of public works, and a total sum of 287,000,000 guilders was reckoned as extraordinary expenditure in 1913–8. Increased expenditure was for the most part met by increase of ordinary taxes rather than imposition of new taxes, but a war profit tax, retrospective to Aug. 1 1914, was established in 1917. A complete reissue of the Tariff Act was made in 1920; several revisions were afterwards made, and the Dutch extended their customs territories, partly by buying out the right of native rulers, until they covered almost the whole colony. In the budget for 1920 provision was made for an export duty on staple products, taxes on the

profits from their production, an increase in excises, a special tax upon the working of petroleum, and a tax on transport.

*Agriculture.*—Sugar remained the chief agricultural product for export. War conditions affected the direction of commerce in this commodity: from the beginning of the century down to 1914 China and Japan and Australia were the chief customers for Javanese sugar; in 1915–8 England and India; later China and Japan reëntered the market. The production in Java in 1918 was 1,778,207 tons.[1] The sugar manufacturers united into a general syndicate with headquarters at Surabaya. The Government cultivation of coffee was abandoned in 1918–9, but the State began to exploit several rubber estates in Java and one in Sumatra, while the State Rubber Development Service was separated from the Forestry Service in 1919.

The following shows the number of estates, cultivating the leading products named, in 1918:—

| | Coffee. | Rubber. | Tea. | Coconuts. | Cinchona. |
|---|---|---|---|---|---|
| Java & Madura | 310 | 393 | 268 | 95 | 104 |
| Outer Possessions | 98 | 284 | 27 | 131 | 4* |

*Sumatra West Coast.

Among cultivations developed or considerably extended were those of kapok and sisal hemp, mainly in Java, manilla hemp in the Lampong districts of Sumatra, and the oil palm, principally in the Outer Possessions. It was estimated in 1917 that Java and Madura contained 63 million coconut palms, the Outer Possessions 44 million, of which 60 million were yielding nuts. The estimated annual production of copra was 368,000 tons in Java and Madura, and 213,000 tons in the Outer Possessions; in Java about 200,000 tons were used in the local oil factories. The large estates are not extensively planted with coconut palms: the production is almost wholly from native sources; but the Government started cultivation in 1913. The rice harvest in Java and Madura in 1919 was estimated to yield 3¾ million tons of hulled rice: information for the Outer Possessions is lacking. But the export of rice, maize, and other foodstuffs was prohibited, for the demand was in excess of the supply.

In 1919 there were 24 important irrigation works under construction in Java; no irrigation works on a similar scale existed elsewhere in the islands, excepting Bali, although, following upon an enquiry by the Government in 1910 in Sumatra and Celebes, some lesser works had been carried out.

*Live stock.*—Estimated numbers in 1918 were:—40,000,000 cattle, 2,500,000 buffaloes, 300,000 horses, 3,000,000 goats, 2,500,000 sheep, 1,000,000 pigs.

*Teak Forests.*—The area of these in Java and Madura was estimated in 1918 at 730,000 hectares, of which 36 % was organized in forestry districts under the State Forestry Service. The export of teak, 38,277 cubic metres in 1912, fell to 50 c.m. in 1917 and 1,185 c.m. in 1918, though the amount felled was not greatly lessened. The teak forests are of such outstanding economic importance that all other forests are classed in contradistinction as "wild," but the Forestry Service extended its supervision over them, and an experimental forestry station was established in 1913.

*Mining.*—The Ombilin collieries near Sawa Lunto and those of Bukit Asem near Tanjong in Sumatra, those in the island Pulo Laut off the S. E. coast of Borneo, the Banka tin-mines, and gold and silver workings in the Benkulen district, Sumatra, were worked by the Government, which in addition received five-eighths of the profits of the Billiton tin-mines. Private concessions for working coal and oil and associated products ceased to be obtainable in 1919, except under special contract with the Government. The production of the coal-mines in 1918 was as follows:—Ombilin, 504,201 tons; Pulo Laut, 121,421 tons; Bukit Asem, 50,300 tons, but the last was more fully developed after the Government took over the concession in 1919, in which year production reached 100,000 tons. Over half the total output from Ombilin and Pulo Laut was used in Government services; the rest was sold for bunkering at the ports of the respective fields, Emmahaven and Stagen, or exported thence as freight coal for bunkering at other ports in the archipelago.

Petroleum concessions had been granted to the number of 61 down to 1918, and 26 were sanctioned. The principal oilfields were in Surabaya and Rembang (Java), Muara Enim and other points in Palembang and Langkat and Perlak (Achin) in Sumatra, Tarakan I. and the Mahakkam delta in S. and E. Borneo, and Ceram. The Royal Dutch, Shell and subsidiary companies controlled the trade and working. In 1918 crude oil was produced to the amount of 1,764,203 tons, and among exports were benzine and gasoline, 317,073,000 litres; kerosene, 379,044,000 litres; residues, 291,057,000 litres; turpinol (a substitute for turpentine), 2,556,000 litres; paraffin wax, 21,945 tons; candles, 4,080 tons; lubricating oil, 24,529 tons; asphalt, 1,719 tons; greases, 232 tons.

The production of gold, principally from Benkulen, Padang (central Sumatra) and the northern peninsula of Celebes amounted to 3,893 kgm. in 1917, and that of silver to 34,014 kilograms. The value of diamonds produced (in Borneo) in 1917 was 55,300 guilders, and in 1918, 116,360 guilders.

[1] Metric tons are quoted throughout this article.

*Manufacture.*—The disturbance of international commerce during the World War resulted in some extension of home manufacture in Netherlands India, and the same effect was produced by the increasing difference between the high wages in European and other manufacturing countries and the low wages paid to native workers in Netherlands India, though this was partly counterbalanced by the low scale of production in the latter. Among manufactures noted for special development were ironfounding (but mechanical works suffer from the lack of skilled labour), and those of edible and essential oils, bricks and tiles, cardboard, rubber wares, cigars and cigarettes, chocolate, etc. A special division of industry was established in 1918 in the Department of Agriculture and Commerce, and the first official annual fair for Netherlands India was organized in 1920 in a building erected at Bandung.

*Commerce.*—Exports and imports (exclusive of bullion, etc.) were valued as follows: in 1913, exports, 627,000,000 guilders; imports, 462,000,000 guilders; in 1918, exports, 676,000,000 guilders; imports, 537,000,000 guilders. The number of foreign firms maintaining representatives in Netherlands India has increased considerably, and the Government has extended its measures for fostering commerce, as for example, by maintaining sample departments or exhibitions in European countries, the U.S.A., Australia, S. Africa, and Japan. The following figures of quantity of some of the chief exports show how the effects of the war operated favourably or adversely:—

| | 1913. | 1918. |
|---|---|---|
| Sugar | 1,471,423 tons | 1,574,201 tons |
| Tea | 26,548 " | 30,452 " |
| Rubber | 7,134 " | 44,096 " |
| Coffee | 28,939 " | 7,357 " |
| Tobacco | 87,832 " | 8,050 " |
| Copra | 229,339 " | 68,578 " |
| Coconut Oil | 1,682 " | 33,237 " |
| Pepper | 18,965 " | 25,899 " |
| Tapioca & Cassava products | 105,532 " | 28,129 " |
| Kapok | 10,145 " | 9,253 " |
| Ground-nuts | 20,141 " | 8,080 " |
| Tin | 27,645 " | 11,584 " |
| Petroleum | 466,529,000 litres | 379,044,000 litres |

Examples of the manner in which the destination of exports altered have been mentioned above: many exports were diverted during the war from the mother-country as *entrepôt*, and went direct to their destinations. The chief imports are soft goods, machinery, iron and steel, hardware, food-stuffs, and artificial manures.

*Communications.*—Java has long possessed an excellent road-system, and it is a settled policy to use the road as a first means of opening up new districts in the Outer Possessions. In 1918 1,738,587 guilders were spent in Java and Madura, and 3,889,580 guilders in the Outer Possessions, on the construction and maintenance of roads and bridges. The Government maintains a number of motor services, as in Palembang, Benkulen, and Sumatra West Coast, as well as in Java (Cheribon-Kuningan). The length of State railways in 1920 was: in Java 1,568 m. of standard gauge (1·067 metre) and 65 m. of narrow gauge (0·6 metre); in Sumatra West Coast 153 m. standard gauge; in S. Sumatra 151 m. standard gauge; in Achin and dependencies 320 m., gauge 0·75 metre. Private lines amount to 156 m. in Java, 260 in Eastern Sumatra (Deli Co.); and in Java there are about 1,375 m. of steam tramways under private management. Water power plants were established in the Chatur valley for the service of the State railway workshops at Madiun (Java) in 1917, and another power station has been set up at Lake Tais to supply the gold-mines in Benkulen (Sumatra). Extensive works were in construction or planned. The chief ports in 1920, according to tonnage of vessels using them, were Tanjong Priok (the port for Batavia), Surabaya, Semarang, Cheribon, and Tegal in Java; Padang, Belawan Deli, and Sabang in Sumatra; Balikpapan in Borneo, and Macassar in Celebes.

*Recent History.*—Slow methodic progress in development, very thoroughly carried out, continued as the characteristic of Dutch administration in Netherlands India. It is probably correct to indicate, as the most difficult internal problems, the reconciliation of European with native interests with justice to both, and the relations between Mohammedanism and the State. As for external relations, concern is sometimes expressed as to the relatively defenceless position of the colony against aggression: a commission reported on this matter in 1913. It was partly this consideration which dictated the strict neutrality of the Netherlands during the World War (for obviously the Dutch possessions were at the mercy of the British fleet): but so far as apprehension found expression as regards any particular Power, that Power was Japan, a fact doubtless associated with the marked development of the economic position of the Japanese in the archipelago. The internal condition of the Outer Posses-

sions was for the most part peaceable: the long-standing strife in Achin was almost stilled by 1912, though sporadic outbreaks have occurred since; the warfare in Gowa (Celebes) since 1905 was brought to an end in 1911 and the country annexed. In 1914 there was a revolt of Young Chinese in Mampawa (Borneo), and slight native disturbances in Sumatra and Lombok, the latter apparently arising out of rumours of a Dutch defeat at the hands of Japan. Military garrisons had to be maintained in parts of Bali till 1914.

Disputes arose with Portugal when it was endeavoured to delimit the frontier between Dutch and Portuguese territory in Timor according to the treaty of 1904. The Dutch claims were allowed by M. Lardy, a Swiss member of the Hague Court of Arbitration, acting as arbitrator in 1914. (O. J. R. H.)

**NEVADA** (*see* 19.450).—The pop. in 1920 was 77,407; in 1910, 81,875, a decrease of 4,468, or 5·5% as against an increase of 93·4% for the preceding decade. The native whites in 1920 numbered 55,897; foreign-born whites 14,802; Indians 4,907. The density of pop. in 1920 was 0·7 per sq. mile. The urban pop. (in places having more than 2,500 inhabitants) was 19·7%, the rural 80·3%. Reno, with a pop. of 12,016, an increase of 10·6% over the 1910 figures (10,367), was the only city having more than 5,000 inhabitants.

*Agriculture.*—The number of farms in 1920 was 3,163. The value of farm property increased 1910–20 from $60,399,365 to $99,779,666. The value of crops harvested more than doubled from 1915 to 1920 largely owing to higher prices. In 1919 and 1920 the value of agricultural products surpassed mineral production with every indication that this predominance would continue. Sheep and cattle form Nevada's most important agricultural output. The Agricultural Experiment Station at the university of Nevada, the Department of Range Management, a state Board of Stock Commissioners, the state Veterinary Control Service, the Agricultural Extension Division of the university and the Federal Bureau of Animal Industry—all show rapid development of experimental research as to poisonous plants, the handling of live stock on white-sage ranges, the haemorrhagic disease of cattle which is peculiar to the Pacific slope and inter-mountain country, tuberculosis control, particularly among dairy herds and pure-bred beef herds, and the control of rabies. Predatory animals are abundant in so thinly settled a state and rabies infection from them, especially the coyote, is a constant menace to domestic stock. A state Sheep Commission enforces quarantine laws. Nevada honey has a high reputation but is limited in amount because alfalfa, the chief honey plant in Nevada, is cut before it has fully bloomed.

The better utilization of water supply for irrigation and power is one of the most pressing needs. The riparian law, common to England and the eastern states, was found to be ill-suited to Nevada. Early state laws, therefore, gave vested rights in water to those who used it for irrigation. Increase of settlement led to difficulties of adjudication and during the decade 1910–20 many of these have been settled by the courts. The result will be to make available more irrigable land and thereby to increase the population which can comfortably be supported thereon. The fuller use of Lake Tahoe for storage was in 1921 a subject of negotiation with California. The Colorado river project includes five other states with Nevada. The first unit proposed by this plan to provide for irrigation, flood control and power is a great reservoir to be created by building a 700-ft. dam at Boulder Canyon, Nevada. Legislation for this purpose was being considered by Congress early in 1921. The development of underground waters has been encouraged by the state since 1915 through study by commissions, through Irrigation District and Drainage District laws and through enactments favouring the sinking of artesian wells. The Pittman Act of Congress offers favourable conditions for the acquirement of public lands in Nevada through the development of underground waters. Since 1919 California and Nevada have maintained a coöperative snow survey.

*Minerals and Manufactures.*—From 1907 metal production steadily increased until it reached its peak in 1917, in which year gold, silver, copper, lead and zinc were produced to the value of $54,424,580. In 1919 production decreased more than 50% from that of 1918, owing to a variety of causes which included exhaustion of ore bodies, scarcity of labour, decline in metal prices and high operating costs. Exhaustion was so rapid that the production of gold declined from 551,683 fine oz. in 1915 to 219,695 in 1919. During the same period production of silver declined from 14,459,840 fine oz. to 6,863,580. Until 1918 copper production increased remarkably, being 68,636,370 lb. in 1915 and 122,794,704 lb. in 1917. This had declined in 1919 to 52,331,175 lb., chiefly owing to the sharp fall in market value.

From 1914 until 1918 extensive developments were made in tungsten producing mines. At the time of the signing of the Armistice in 1918, it appeared the Nevada could supply the United States with that metal. When the World War terminated the price of tungsten dropped below the cost of production, resulting in the suspension of all tungsten mining in the state. Mining in Nevada in 1920 and 1921 was in a greatly depressed state. All copper-mines suspended production, as did most lead and zinc operations. Production of gold and silver materially decreased, and those metals were the only two the state continued to produce extensively. The high price of silver which prevailed well into the middle of 1920 kept alive the production of that metal. Although in 1919 there were produced only 6,863,580 fine oz. as compared with 10,000,599 in 1918, the gross value for 1919 was not greatly diminished because of high market price. In 1919 silver averaged in value $1.12 per fine ounce. In 1920 oriental purchases so largely declined that the market dropped below the price fixed in the Pittman Silver Purchase Act. This law then enabled producers to sell their silver to the U.S. Mint at the fixed price of $1 per fine oz., and to continue production which otherwise would have ceased. Much attention was devoted to the so-called commercial minerals. While statistics were not available, it was known in 1921 that gypsum, fluorspar, diatomaceous and fuller's earths, alum, potash, sulphur and other rock products were being produced in commercial quantities.

Other minerals commercially developed were quicksilver, antimony, manganese and platinum. The principal silver-producing district is Tonopah, Nye county, but there is also extensive production at Virginia City, Storey county; Rochester, Pershing county; Eureka, Eureka county; and Pioche, Lincoln county. Most of Nevada's gold comes from Tonopah, Manhattan and Round mountain in Nye county, Goldfield in Esmeralda county; Virginia City, Gold Hill, and Silver City in Storey county; and Jarbridge and Gold Circle in Elko county. Copper is produced chiefly in the Ely district in White Pine county. The Mason Valley district in Lyon county and the Luning district in Mineral county have extensive deposits. Lead mines are located principally in Eureka, Mineral, Clark and Lincoln counties. Zinc comes almost entirely from Clark and Lincoln counties. The larger tungsten deposits are in Pershing, Humboldt, Mineral and White Pine counties. Quicksilver is found principally in Nye and Mineral counties. Platinum is mined at Good Springs in Clark county. Since 1919 extensive developments have been carried out at Gold Hill on the Comstock Lode in Storey county, and give promise of an extensive revival of precious metal output in that district, which was formerly of great importance.

The value of all manufactured products increased 35·3% between 1909 and 1914 and 42·2% between 1914 and 1919, but the value added by manufacture in 1919 showed a decrease from 1914 of 5·7%, due to the decrease in the smelting and refining of copper.

*Transportation.*—Since 1910 the Western Pacific railway has acquired a part of the Nevada-California-Oregon line and has altered it to broad gauge, thus making connexion with Reno, the largest town in the state. Several short lines have been built. The Las Vegas and Tonopah Railway Co. discontinued operation from Beatty to Las Vegas in 1918. The Legislature of 1919 designated the line as part of the state highway system and the Highway Department acquired the road bed, which in 1921 was being converted into a modern highway. Under the Federal Aid Road Act of 1916 $962,684 became available for use in Nevada, and by the amendment of 1919 an additional sum of $2,564,591. The state took steps to provide its quota and the Overland Trail Club received promises of further aid from California and from the Lincoln Highway Association. The frequency of waterspouts in some areas and of drift sand in others presented difficulties which were being overcome by the state Highway Commission. A scenic highway was opened on the W. side of Walker lake as a part of the North-South highway. The Phipps Highway bill, before Congress early in 1921, provided for Government aid in proportion to area of public lands in the state, and should greatly promote road building in Nevada, since 90·6% of the area of the state was still at the time Federal property. The Railroad and Public Service Commission of Nevada was seeking to render permanent the elimination of the "back-haul rates" removed by the Interstate Commerce Commission in March 1918. The inter-mountain region was asking for "graded rates" in 1921. The 25% increase in freight rates, in Aug. 1920, resulted in the cessation of much mining activity and a loss of markets for live stock.

*Government, Education and Finance.*—State social service has been extended through numerous commissions and a few new departures, such as the industrial school and the grant of state aid to the Florence Crittenton Home. The Nevada Historical Society, made a state institution in 1907, has published six volumes of historical papers besides numerous pamphlets. The Orphans' Home is noteworthy in that it educates its children in public schools and does not dress them in uniform. The necessity of securing increased public revenues and equalizing the burden of taxation gave rise to the Tax Commission in 1913. Nevada was one of the first states to have industrial insurance. An extensive building programme for state institutions was begun in 1917. It includes new prison and asylum structures, a Heroes' Memorial Building, additions to the Orphans' Home and the Nevada School of Industry, and several new buildings at the university of Nevada. A branch of the Federal Bureau of Mining Extension was removed in 1920 from Colorado to the university of Nevada. All Federal experimental work relating to rare and precious metals is conducted at this station, which works coöperatively with

the Mackay School of Mines at the university. A Federal wireless station was installed to serve the air mail service. Several public service divisions have been added to the extension work of the University, which joined the Association of American Universities.

The salary of Nevada teachers advanced about 50% between 1914 and 1920, reaching an average of $1,362 in the latter year. Retirement salary provision, consolidation of schools, standardization of small schools, evening schools for Americanization, vocational education including part-time training, industrial rehabilitation and thrift education were among the progressive movements undertaken. The bonded debt of the state, Jan. 1 1921, was $1,382,500. In 1915 the constitution was amended to permit a state debt amounting to 1% of assessed valuation of property. The state receipts for 1920 were $1,874,447, and the assessed valuation of all property in the state was $213,421,398.

*History.*—The Progressive party maintained an organization in Nevada in 1912 which polled a vote second to that of the Democrats. The Democratic party continued in undivided power until the election of 1920 gave many important offices to Republican candidates. Emmet D. Boyle, Democrat, was elected governor in 1915 and re-elected in 1919.

Amendments to the constitution of Nevada were made in 1909, 1911, 1913, 1915, and 1919. The most important were those for the recall and female suffrage in 1911 and 1913. The state prohibition law was enacted, pursuant to a direct vote of the people cast Nov. 5 1918. The Legislature ratified the 16th Amendment (income tax) to the Constitution of the United States in 1911, the 17th (direct election of senators) in 1913, the 18th (prohibition) in 1919 and in the same year endorsed the proposed woman suffrage amendment. In a special session held Feb. 7 1920 it ratified the 19th Amendment (woman suffrage). Legislative sessions are limited to 60 days. Budget legislation was adopted in the session of 1919 and amended in 1921. The state is divided into 17 counties, two new ones having been created in 1911 and 1919. In 1921 a four-year term of office was provided for county officers. The same session provided for criminal execution by use of lethal gas.

In the World War Nevada furnished 5,535 men to the army, navy and marine corps, of whom 3,211 were inductions, 2,324 volunteers. Only one state, Montana, surpassed Nevada in the percentage of men contributed. Nevada gave 160·4% surplus of volunteers, one out of every 9 men of military age, one out of every 33 inhabitants. A surplus of 304·7% above the true proportion was given to the draft, and the selected men were turned over to the military authorities without expense to the Federal Government. The following figures show the amount subscribed in the five Liberty loans: First, $2,943,750; Second, $3,472,200; Third, $4,793,400; Fourth, $5,996,150; Fifth, $3,668,700; a total of $20,874,200, nearly five millions more than the state's quota. In 1919 the Legislature passed a land settlement Act providing a bond issue of $1,000,000 for soldier settlement work in coöperation with the Federal Government.

(J. E. W.*)

**NEVILL, LADY DOROTHY FANNY** (1826–1913), English writer, was born in London March 1826, the daughter of Horatio Walpole, 3rd Earl of Orford. She married in 1847 Mr. Reginald Henry Nevill (d. 1878), a grandson of the 1st Earl of Abergavenny. She travelled widely, and had a very large circle of acquaintances, including Disraeli, of whom she was a great admirer, Richard Cobden and Joseph Chamberlain. She was noted for her amusing conversation and powers as a hostess, was a member of the first committee of the ladies' branch of the Primrose League, and was the author of various volumes of entertaining reminiscences: *Recollections* (1906); *Leaves from the Notebooks of Lady Dorothy Nevill* (1907); *Under Five Reigns* (1910); *My Own Times* (1912). She died in London March 24 1913.

Her daughter, MERESIA DOROTHY AUGUSTA NEVILL (1849–1918), was also a devoted and energetic worker for the Primrose League. She was for many years treasurer of the Ladies' Grand Council. She died in London Oct. 26 1918.

See Ralph Nevill, *Life and Letters of Lady Dorothy Nevill* (1919).

**NEVILLE, SIR RALPH** (1848–1918), English judge, was born at Esher Sept. 13 1848, the son of Henry Neville, a surgeon. He was educated at Tonbridge school and Emmanuel College, Cambridge, where he took his degree in 1870. In 1872 he was called to the bar, and established himself in Liverpool, where he built up a large practice. In 1888 he became a Q.C., and returned to London, where he made a marked success. From 1887 to 1895 he sat as Liberal member for the Exchange division of Liverpool, and in 1906 was raised to the bench and knighted. He died at Ventnor Oct. 13 1918.

**NEWBOLT, SIR HENRY JOHN** (1862– ), English poet (*see* 19.463), was knighted in 1915 and was made a Companion of Honour Jan. 1 1922. His *Poems New and Old* appeared in 1912; *Drake's Drum and other Sea Songs* (1914) and *Aladore* (1914). During the World War he was engaged on naval records for the British Admiralty, and in 1902 he published a *Naval History of the War*. His *Tales of the Great War* (1916), *The Book of the Happy Warrior* (1917) and *Submarine and Anti-Submarine* (1918) were written primarily for the young. He also published *A New Study of English Poetry* (1917); *Poetry and Time* (1919). His chief contributions to war poetry appeared in 1918 as *St. George's Day and other Poems*.

**NEW BRUNSWICK** (*see* 19.464).—The pop. of this Canadian province, which was 351,889 in 1911, increases but slowly. The former exodus to the United States and the western provinces of Canada has been largely arrested. The only towns having over 5,000 inhabitants in 1911 were Fredericton, the capital, 8,000; Chatham, 5,500; St. John, the chief shipping and commercial centre, 63,000; and Moncton, a large railway centre, 25,000.

The province sends 10 senators and 11 members of the House of Commons to the Federal Parliament. The Legislative Assembly consists of 48 members, and the executive of seven.

The various grades of schools are supported by legislative grants supplemented by local taxation. Schools in the cities are managed by boards of trustees, one half appointed by the Government and one half by the city corporation. School attendance has varied but little since 1910: in 1917 about 65,000 pupils were enrolled, with about 2,000 teachers. The three degree-giving universities are the old university of New Brunswick at Fredericton; Mount Allison University at Sackville, and St. Joseph's College at St. Joseph.

*Industries.*—It is estimated that there are about 22,000 sq. m. of arable land in New Brunswick, the greater part of which has not been brought into cultivation. In fact, the actual area under cultivation had been for some time slowly decreasing until the outbreak of the World War. Wheat-growing, which had become unprofitable, was then stimulated by prices and the demand for production for overseas consumption. Other agricultural products were stimulated in the same way, and a gratifying increase was noted for several years. Over 7,000 sq.m. had been taken up in 1921, of which 2,260 sq.m. were under crop. The production of wheat increased from 267,000 bus. in 1915 to 464,400 in 1920, with an average for the five years of 452,850; oats from 5,600,000 bus. to 9,118,000 with an average of 6,437,200 bus.; potatoes from 5,772,000 bus. to 15,510,000 bus., with an average of over 8,000,000 bus.; hay from 791,000 tons to 871,700 tons, with an average of 854,400 tons. Over 6,000 ac. in the Blue Bell tract were for sale in 1921, and along the Bay of Fundy are very large areas of reclaimed marsh land famed for their productivity year after year without the use of fertilizers. There are also extensive areas of naturally suitable land for production of wool and mutton, so that there was altogether room for large agricultural development. Dairying is encouraged by the Legislature. Cheese and butter factories are scattered throughout the province. A maritime dairy school is maintained at Truro, and cheese and butter boards have their headquarters at Sussex.

Of the 7,500 ac. forest land still in the hands of the Crown, over 73% supports merchantable timber, of which about 40% is a hardwood stand. The value of the lumber cut in 1918 was $12,190,000. The total pulp production was 66,619 tons, valued at over $5,000,000.

The value of the fisheries in 1919 was approximately $5,000,000, a decrease of $1,320,000 as compared with the previous year.

Though not a manufacturing province in the sense of Ontario and Quebec, New Brunswick has made very steady progress. In 1900 the capital invested was $20,750,000, and in 1918 $74,500,000, with an increase of output from $21,000,000 to $68,333,000. New Brunswick has 300,000 H.P. available, of which only about 15,000 had in 1921 been developed. At Grand Falls is the largest undeveloped waterpower in eastern Canada.

*Communications.*—The roads have been greatly improved, the province taking advantage of the appropriations of the Dominion Government in connexion with the general movement in Canada for good roads. The Inter-colonial Railway, a part of the Canadian National Railways system, is still the main line of communication.

The Canadian Pacific also runs through the province, with a terminus at St. John, and the National Transcontinental from Winnipeg has its terminus at Moncton. By means of the C.P.R. and Maine Central the province has communication with the United States. Various lines of steamers run, chiefly from St. John, to American and Canadian ports. St. John is also one of the Atlantic ports for transatlantic lines of steamers. (W. L. G.*)

**NEWCASTLE-UPON-TYNE** (*see* 19.472).—The pop. increased from 266,603 in 1911 to 274,955 in 1921. The borough returns four members to Parliament. To the list of degrees granted by the college of science incorporated with the university of Durham has been added a degree in commerce. During the World War the shipbuilding industry and the production of ordnance and ammunitions showed very marked activity and development.

**NEWFOUNDLAND** (*see* 19.478).—The census of 1911 showed 242,619 inhabitants, including 3,949 residing in Labrador, an increase for the decade of 21,635, or 9·79%, against 9·37% for the previous decade. Denominationally the distribution was: Roman Catholic, 81,177; Church of England, 78,616; Methodist, 68,042; Salvation Army, 10,141; others, 4,643. The pop. of St. John's, the capital, was 32,292, a 9% increase. The Registrar-General's estimate of total pop. at end of 1919 was 264,569, but a reduction was expected for 1920 because of abnormal emigration due to economic depression, the figures being: inward 10,996; outward 15,422.

*Economic Conditions.*—Few countries prospered more during the decade 1910–20 than Newfoundland, thanks to increasing prices for her fishery products (especially during the war period, due to scarcity of food-stuffs in Europe, and despite the withdrawal of 10,000 young men from her industries to undertake active service with the army and navy); to the development of her pulp and paper industry and her iron mining; to the corresponding growth in subsidiary local industries, farming, logging, manufacturing, etc., and to the increased purchasing power of the people to which, besides the above factors, the war expenditure, some $15,000,000, or one-third of her total debt, contributed materially. Unfortunately this favourable condition no longer exists.

*Finance.*—Each of the four years from 1917 showed a marked increase in revenue with a handsome surplus, that for 1918–9 being $2,853,000. The figures for 1919–20 were: revenue $10,597,575, expenditure $9,247,006, leaving a surplus of $1,350,509 notwithstanding that large additional grants were made to various public services because of the then existing prosperity. The public debt as at June 30 1920 was $43,993,035. The imports for 1919–20 were $40,533,388, exports $34,855,447. Distribution of imports was: from Britain $4,637,074; Canada $18,767,238; United States $15,414,067; other countries $1,715,009. Distribution of exports was: to Britain $6,411,967; Canada $2,802,859; United States $4,426,142; other countries $21,424,479. Figures of revenue, imports and exports, represented a three-fold increase in the decade 1910–20 but imports from Britain remained almost stationary owing to proximity and more aggressive trade methods of the United States and Canada.

During the latter half of 1920 depression became manifest, emigration increased, business difficulties arose, fishery prices declined, imports lessened and the economic sky became overcast. Conditions in the spring of 1921 were very serious; customs revenue, representing nine-tenths of the total, had declined $2,500,000, roundly, in ten months; a shortage of nearly $2,000,000 for the fiscal year was feared; and financial embarrassments otherwise were thought to threaten the national solvency. This condition was due in part to world depression, but also to an attempt of the Government to enforce a policy of "control" over the marketing of codfish in foreign countries, by regulations fixing minimum prices for the sale of the commodity, and also restricting the times at which fish might be sent, the quantities forwarded and the terms of sale in different countries. This policy, after being operated from Nov. 1919 to Dec. 31 1920, or over part of two marketing seasons, was virtually abandoned. Its opponents contended that it was economically unsound, because it violated the law of supply and demand; its advocates could only plead that because of world depression it did not have a fair chance to prove its merits. It was estimated that incidentally through falling markets in Greece, Italy, Spain, Portugal, West Indies and Brazil, where Newfoundland codfish principally goes, and the workings of the Government policy, losses estimated at $3,000,000 to $4,000,000 would be suffered in marketing the catch of 1920, valued at $12,000,000, causing heavy losses to banks, business people and others interested, and reacting seriously on the whole community.

*Fisheries.*—The fisheries continue to be the mainstay of the country as in years gone by, and in 1921 still represented nearly 80% of the exports, furnishing $25,000,000 out of $28,000,000 for 1919–20. The chief is the codfishery, prosecuted mainly by boats, smacks and large schooners around the coast of the island, along the seaboard of Labrador, and off the Grand Banks, the product being salted and dried in the sun and exported in that condition. Attempts at the development of a cold-storage industry have been made, and a large warehouse for this purpose has been erected in St. John's. During the World War a cargo of cold-stored fish was taken to England by the auxiliary cruiser "Bayano" and was said to have given much satisfaction. Similar shipments were not continued but regular liners plying to Britain enlarged their cold-storage capacity to take larger quantities; British capital was also introduced into the business, and the smoking of fish for the British markets has been promoted as an important adjunct. The seal fishery has declined in scope in recent years, because of the withdrawal of several of the larger and more powerful steamers for war work, which have not returned, the loss of others through ocean perils, and the excessive cost of building new ships during the war. The fleet, moreover, met misfortune after 1918 for three successive seasons, and to induce the small flotilla of nine ships to operate in 1921 the Government removed all restrictions on the conduct of the industry, and a catch of 101,452 seals valued at $171,243 resulted, representing about two-thirds of a normal catch for such a fleet. The herring fishery, which enjoyed an increase in values like the codfishery during the later years of the war, suffered afterwards from the reaction caused by the competition from British and other markets not then active. The whale fishery had been gradually declining, and in 1920 no whalers operated at all owing to low prices for the products. The lobster-canning industry also declined, owing to depletion of the species, which being slow in reproducing, suffered from overfishing in the past. The Government inaugurated a campaign for better methods of curing and packing fishery products, hoping thereby to secure better prices. The value of the fishery products for 1919–20 was: codfish $23,274,666; cod-oils $2,162,724; seal-skins $170,331; seal-oils $262,353; herrings $1,235,864; lobsters $325,769.

*Forest Resources.*—The forest areas are estimated at about 15,000 sq.m., and are chiefly used for making pulp and paper, as spruce is the main growth. Formerly pine was cut and exported, finding a good market in South America, but several areas were depleted and in more recent years the pine has been absorbed altogether by the local demand. The paper-making enterprise of Lord Northcliffe and his associates at Grand Falls midway through the interior, with about 3,500 sq.m. of territory, steadily expanded. In 1920 it produced 215 tons of newsprint paper daily, with 25 tons of ground-wood and 25 tons of sulphite pulp, and plans were being made for enlarging it to double its capacity. Pulp mills at Bishop Falls, 10 m. distant, formerly held by separate owners, were absorbed, and it was estimated that a pulp output of 200 tons daily would be manufactured at Grand Falls after the works were enlarged. A company with capital raised in Norway put under construction for starting operations in the autumn of 1921, mills on the Terranova river which empties into Bonavista Bay, which would produce 50 tons strong sulphite pulp daily. It controls an area of 1,250 sq.m., and was later expected to double this output. The export in 1920 was 19,864 tons of pulp valued at $334,276, and 80,719 tons of paper valued at $4,725,660. In addition 292 saw-mills cut during the year, for local consumption, 25,155,776 ft. of lumber, valued at $1,006,251.

*Mineral Resources.*—Mining operations of late years have been devoted almost entirely to the winning of hematite iron from deposits at Bell I. in Conception Bay, 18 m. from St. John's, owned by the Dominion and Nova Scotia Steel Cos. and forming the basis of the proposed "British Empire Steel Corporation" into which these concerns are to be merged. Copper mines were worked in a small way until 1919, but after that, owing to various causes, nothing was done for two years, though a revival in this industry was expected. The Anglo-Persian Oil Co. contracted with the Government to begin during the summer of 1921 a scientific exploration of oil-bearing areas in the country and their practical working if warranted, and the Government undertook to develop coal beds on the W. coast to secure fuel for the railway service, as all the coal required for every purpose in Newfoundland had had to be brought from the adjacent island of Cape Breton. In Newfoundland can be found evidences of the occurrence of almost all known minerals, but through lack of an efficient Geological Survey, and in consequence the want of prospecting and other researches in the interior, and because of the difficulty in attracting capital to the country, little progress had been made in developing them. In the past iron pyrites have been mined at Pilley Is., on the N. coast, chrome iron at points on the W. coast, silver-lead ore in Placentia Bay, coal at Grand Lake, in the interior, and petroleum at Parson's Pond on the N.W. seaboard; petroleum is still being worked and the produce is used at the gas works in St. John's. The export of iron ore for the five years to 1920 averaged 750,000 tons, valued for export purposes at about $1.25 per ton; 16,000 tons of copper ore, valued at $205,000, were shipped in 1916–7, but only one-third of this quantity was sent out in 1917–8.

*Communications.*—In addition to the 614 m. of railway previously existing, the Morris Government in 1909 contracted for the construction of six branches, aggregating 354 miles. Four of these branches, totalling 277 m., were completed by 1917, but the

remaining two had to be abandoned owing to the war, and seemed, in 1921, unlikely to be built in the near future unless under some revision of the entire railway problem which the Squires Government had in hand. Messrs. Reid, who operated the railway under a contract, claimed that conditions similar to other parts of the world had applied here, making their enterprise unprofitable, and at the 1920 session of the Legislature the Government provided for a commission (half chosen by the Government and half by the Reids) to study the problem; and it arranged for a loan of $1,000,000 to be applied for the purchase of rolling stock and equipment. Subsequently the Government took a more direct part in the actual operating of the road, and the railway question promised to be of first importance at the 1921 session.

Telegraph extension has been gradually carried out until almost the entire seaboard of the island is girdled with lines, the whole being operated as a public utility under Government control. Wireless stations at important points around the Newfoundland coast, and along the coast of Labrador, have been constructed or previously existing ones improved, and plans were in 1921 being made for directional wireless stations at points where shipwrecks are frequent. During the war period the British Admiralty built a high-power station at Mt. Pearl, 6 m. W. of St. John's, which proved of great value and continued to be operated as a naval auxiliary. In July 1920 a wireless telephone installation was established on Signal Hill, St. John's, where Marconi had received his first wireless telegraph signals 18 years previously, and communication was maintained with the liner "Victorian" during her voyage across the Atlantic with the members of the Imperial Press Conference. Negotiations for a contract with the Newfoundland Government for permanent installations were in progress in 1921.

The telephone system at St. John's and an independent line operating on the N. side of Conception Bay were completed, an entirely new equipment provided for St. John's, and steps taken to link the whole of Conception Bay with the capital.

Steamship services with Britain, Canada and the United States were seriously dislocated during the war period, but were gradually restored, though pre-war efficiency had not been attained in 1921.

*War Record.*—On the outbreak of hostilities in 1914 the Government of Premier Morris took measures to ensure Newfoundland's active participation in the struggle. Simultaneously with Canada's offer of 30,000 men, Newfoundland offered to raise a military contingent of 500 men, and to increase the existing naval service (a branch of the British naval reserve formed in 1899) from 500 to 1,000; these offers were accepted by the Imperial authorities.

The first military contingent proceeded to England with the original Canadian force, being conveyed in the Newfoundland steamer "Florizel" and, being subsequently strengthened, became the Newfoundland Regt. and participated in the fighting in Gallipoli, then served in Egypt, fought in France and Flanders, and continued in the line until the Armistice, when it formed part of Gen. Plumer's army of occupation in Germany. During this period its membership was renewed three times and some 6,500 men, all told, were enlisted, while a forestry battalion of 500 was likewise formed and served in Scotland. Naval enlistment was also carried on and some 2,000 men were recruited for this force, which distinguished itself in every branch of British naval activities but especially in manning small craft and in furnishing boat crews for boarding purposes for the 10th Cruiser Squadron, which enforced the blockade off the N. of Scotland. The fatalities in the regiment were 1,251 and in the naval reserve 187.

*Political History.*—The Government of Sir Edward (afterwards Lord) Morris was reëlected in Nov. 1913 for a four-year term, defeating an opposition party composed of the followers of Sir Robert Bond and Mr. William Coaker, the latter president of the Fishermen's Protective Union, a coöperative organization that developed greatly afterwards. A few months later Sir Robert Bond resigned his seat in Parliament, being dissatisfied with some statements of Mr. Coaker, and the opposition leadership was assumed by Mr. James Kent, previously Attorney-General in the Bond Cabinet (1909). A year later Mr. Kent was appointed to the Supreme Court Bench. After the outbreak of the World War party lines were largely abandoned and the opposition combined loyally in assisting in all measures to promote the colony's part in the war. After Mr. Kent's appointment to the Bench, he was succeeded as opposition leader by Mr. (afterwards Sir William) Lloyd, another legal member of the opposition group. In 1917 a National Government was formed, the Cabinet being increased to 12 members, Government and opposition taking 6 places each, Sir Edward Morris continuing as Premier and Mr. Lloyd becoming Attorney-General. A measure extending the life of Parliament, because of the war, was enacted, and twice extended subsequently, making two years altogether. At the end of 1917 Sir Edward Morris resigned the premiership and his seat in the Legislature. He left the colony and settled in England, being raised to the peerage as Baron Morris of St. John's and of Waterford. He was succeeded in the premiership by Mr. Lloyd, who during the ensuing year was created a Privy Councillor and made a K.C.M.G. On the formation of the Lloyd administration, the Hon. Richard Squires, Attorney-General under Sir Edward Morris and Colonial Secretary under the National Government, withdrew and opposed the administration. In May 1919, owing to differences between the Fishermen's Union wing of the Government and another wing, led by Sir Michael Cashin, Minister of Finance, the Lloyd Ministry was defeated and Sir Michael Cashin became Premier, the Fishermen's Union group withdrawing. Sir William Lloyd was subsequently appointed registrar of the Supreme Court. Later in the year the Fishermen's Union party joined with the followers of Mr. Squires, and at the general election in Nov. 1919 this combination carried 23 seats against 13 which fell to the Cashin party, and Mr. Squires succeeded to the premiership. Mr. Coaker, whose following was the strongest of any in the Legislature, took the portfolio of Fisheries, and inaugurated the new fishery policy described above, which continued to be the subject of bitter criticism and unceasing contention.

The legislative programme of the 1919 Government provided for measures for the promotion of the public health; the erection of working men's homes in St. John's; the enlargement of the Old-Age Pension scheme; a campaign against tuberculosis; the creation of a Department of Education and the improvement of this service; the organization of a Department of Trade and Commerce; the enlargement of the activities of the Fisheries Department;, the grappling with the railway problem and improvement of the postal telegraph and postal service; promoting agricultural development; giving adequate recognition to labour; liberalizing the mining laws; remedying defects in the Prohibition law; caring for the returned soldiers, and reducing taxation.

See *Year Book of Newfoundland* (1921); *Newfoundland Guide Book* (1911, ed. D. W. Prowse); P. T. McGrath, *Newfoundland in 1911;* James P. Howley, *Mineral Resources of Newfoundland* (St. John's, 1909). (P. T. M.)

**NEW GUINEA** (*see* 19.486).—Exploration in Dutch (western) New Guinea was systematically continued after H. A. Lorentz had completed his journey to the Snow Mts. in the S. in 1909. The work was continued in 1910–1 by M. Moszkovski, in 1912–3 by A. Franssen Herderschee, and by subsequent explorers, and plans were laid in 1918 for extended exploration of the territory N. of the Snow Mts. and for a descent from them to the S. coast. The hitherto existing administrative division of Dutch New Guinea between the residencies of Ternate, which included northern New Guinea, and Amboina, which included the S. of the island, ceased to work satisfactorily, and in 1920 it was stated that the island administration would be centred in the hands of one official with headquarters at Manokwari.

*Territory of Papua.*—Pop. (est. 1918), 250,000 natives, 962 Europeans. For one year, 1918–9, revenue amounted to £72,121, expenditure to £102,962; exports were valued at £176,247, imports at £258,112. Mineral oil has been discovered in the territory; boring was begun under official auspices in 1912, and was continued more thoroughly in and after 1915; it was determined to keep the exploitation in the hands of the Government for a time, and the Commonwealth and Imperial authorities agreed to contribute £50,000 each toward the fuller investigation of the field at Vailala. Gold has been worked or is known to exist in parts of the territory and adjacent islands. From 1888 (when British New Guinea was proclaimed a colony) down to 1916 gold to the value of £1,436,249 was obtained. On Misima or St. Aignan I. in the Louisiade Archipelago gold was little worked until 1914, when it began to be considerably developed, about 70 whites being settled in the island, which became the most important source of gold in the territory. Agricultural industries are developing (*see* AUSTRALIA).

*North-eastern New Guinea.*—With this territory are included the Bismarck Archipelago (New Britain, New Ireland and other

islands) and Bougainville and Buka of the Solomon Islands. The German administrative capital was successively shifted from Friedrich Wilhelmshafen on the mainland of New Guinea to Herbertshöhe (Kokopo) in New Britain and then to Rabaul on Simpson's Harbour (Simpsonshafen) in the same island, where a new town was laid out. On Sept. 11 1914 a force of the Australian naval reserve was landed at Kokopo, and on the following day the British flag was hoisted. The whole territory was subsequently assigned to Australian administration under mandate. In 1919–20 a Royal Commission of the Commonwealth was unable to agree whether the territory should be attached to that of Papua or administered separately. The European pop. of German New Guinea was estimated in 1914 at 300, and 16,800 ac. were cultivated, mostly under coco-nuts, and these are also the chief economic product of the islands. For one year, 1918–9, exports from the territory were valued at £300,766 (copra, £274,318); imports at £280,980. On the mainland the sago palm, rubber, rice, sisal-hemp and coffee have been cultivated, gold has been worked, coal reported in the Nusa valley, and in 1914 a German commission was instructed to investigate for oil. On the islands, rice, rubber and cacao have been cultivated; zinc, copper and gold reported in Bougainville, and phosphates on the Purdy Islands. The seas yield pearl, trepang and turtle.

**NEW HAMPSHIRE** (*see* 19.490).—The pop. in 1920 was 443,083; in 1910 430,572; a gain of 12,511, or 2·9% as against 4·6% in the preceding decade. The urban pop. was in 1920 279,761 or 63·1% of the whole as against 59·2%, in 1910. The pop. of the eight cities having more than 10,000 inhabitants was:—

| | 1920 | 1910 | Increase per cent |
|---|---|---|---|
| Manchester | 78,384 | 70,063 | 11·9 |
| Nashua | 27,379 | 26,005 | 9·1 |
| Concord | 22,167 | 21,497 | 3·1 |
| Berlin | 16,104 | 11,780 | 36·7 |
| Portsmouth | 13,569 | 11,269 | 20·4 |
| Dover | 13,029 | 13,247 | 1·6 |
| Keene | 11,210 | 10,068 | 11·3 |
| Laconia | 10,897 | 10,183 | 7·0 |

*Agriculture.*—The statistics for farm property, showing the changes from 1910 to 1920, are as follows:—

| | *1920* | *1910* | *Inc.* | *Dec.* |
|---|---|---|---|---|
| Number of farms | 20,523 | 27,053 | | 24·1% |
| Value of farm property | $118,656,115 | $103,704,196 | 14·4% | |
| Average acreage—all land | 126·9 | 120·1 | 5·6% | |
| Average acreage—improved land | 34·2 | 34·3 | | 0·1% |
| Av. value per ac. (farm property) | $45.57 | $31.91 | 42·8% | |

Farms of from 100 to 499 ac. constituted 42·9% of the whole number. Farms of 20 ac. or less had the greatest proportion of land improved, 67·4%; farms of over 1,000 ac. had the least—13·3%. Of all farms 90·6% were operated by owners, 2·7% by managers, and 6·7% by tenants, these percentages being without substantial change from 1910. Native farmers decreased from 24,347 in 1910 to 20,509 in 1920. Percentage of farms mortgaged in 1910, 25·6; in 1920, 31. Increase in expenditures, so far as reported, was in 1920 34% for labour, 2·7% for fertilizer, and 89·1% for feed. Other statistics are:—

| | 1919 | 1909 | Increase per cent |
|---|---|---|---|
| Dairy products sold | $ 9,627,286 | $ 5,130,057 | 87·7 |
| All crops | 23,509,665 | 12,112,260 | 94·1 |
| Cereals | 1,456,628 | 879,631 | 65·6 |
| Hay and forage | 13,616,378 | 7,847,148 | 73·5 |
| Vegetables | 5,228,489 | 2,276,176 | 129·7 |
| Potatoes | 2,952,351 | 1,204,620 | 145·1 |
| Miscellaneous crops | 480,804 | 200,845 | 139·4 |
| Orchard fruits and grapes | 2,420,837 | 730,703 | 231·3 |
| Maple sugar and syrup | 440,250 | 182,341 | 141·4 |

*Forests and Highways.*—The White Mountain National Forest contained, June 30 1920, 433,179 ac. of which 27,860 ac. were in Oxford county, Me., and the remaining 405,319 ac. in Coos, Carroll and Grafton counties, N.H. This forest was in charge of a supervisor with headquarters at Gorham, with headquarters for rangers at Bartlett, Woodstock and Bethlehem. The State Forestry Commission was reorganized in 1909. The state reservations are small, widely scattered areas of about 12,000 ac., but including the important and beautiful Crawford Notch. Between 1910 and 1920 the state constructed approximately 1,000 m. of highways at a cost of $6,100,000.

*Manufactures.*—The state in 1914 produced, in value, ·8% of the total for the United States. The statistics were as follows:—

| | 1914 | 1909 |
|---|---|---|
| Establishments | 1,736 | 1,961 |
| Employees | 85,013 | 84,191 |
| Salaries and wages | $ 46,523,733 | $ 40,391,440 |
| Value of products | 182,843,863 | 164,581,019 |

The 10 leading industries were, in order of value of products, boots and shoes, cotton goods, paper and pulp, lumber and timber products, woollen and worsted goods, foundry and machine-shop products, hosiery and knit goods, leather, flour-mill and grist-mill products, tobacco and cigars, ranging from an annual value of over $46,000,000 in the case of boots and shoes to nearly $2,500,000 for tobacco and cigars. The values of all these products materially increased in the 5-year period, 1909–14, except those of woollen, hosiery and mill products. The proportion of female wage-earners, and of those under 16, decreased. The period displayed little fluctuation in the number of wage-earners employed, 93% of the maximum being the lowest. Manchester showed the greatest stability of employment; it employed by far the largest number of wage-earners, about 26,000; and Manchester, Nashua and Berlin produced about $86,000,000 of manufactured products, four-ninths of those of the whole state. The figures showed a tendency towards the concentration of manufactures in the larger establishments.

*Legislation.*—Important Acts were those establishing a state Board of Conciliation and Arbitration; employers' liability and workmen's compensation; regulating child labour and hours of labour; provision for medical and surgical devices in factories; safety and health of employees; and for reporting of occupational diseases. The Legislature of 1917 enacted a law prohibiting the manufacture and sale of spirituous liquors. The law took effect May 1 1918, superseding local option.

*Finances and Taxation.*—The following figures show the increase in expenditures during the decade:—

| | 1920 | 1910 |
|---|---|---|
| Revenue | $4,344,322.20 | $1,694,636.54 |
| Payments | 5,198,534.62 | 1,662,694.07 |
| Debt | 3,040,524.17 | 1,293,209.33 |
| Bonded debt | 2,589,500.00 | 1,071,070.00 |

The increase in expenditures was on account of increased cost of maintaining public institutions, and for highways. The increase in the bonded debt was nearly all due to the World War. In 1918 the state issued $500,000 of bonds to assist the Federal Government in the war; and in 1919 it issued $1,489,000 in order to increase the war service recognition from $30 to $100 for those who served.

The total valuation of property for purposes of taxation in 1920 was $511,456,583, amount of taxes collected $12,736,651, average rate of taxation $2.37 per $100. There were 115,169 persons paying a poll tax of $5 each, and 11,373 war veterans paying $3 each. The valuation of public service corporations was $52,085,125.

*Education.*—Important work was done in 1918 by the state committee on Americanization. In the parochial elementary schools the principle was established that instruction in designated branches and in administration should be exclusively in English; devotional exercises in any language desired. In the large industrial plants the plan was largely carried out by evening schools for adults. The system of public instruction was reorganized by the Legislature of 1919. In the bill "the work of Americanization in teaching English to non-English-speaking adults, and in furnishing instruction in the privileges, duties and responsibilities of citizenship is hereby declared to be an essential part of public-school education." The governor and council appoint a State Board of Education of five citizens who are not technically engaged in education. This Board has the powers formerly resting in the superintendent of public instruction, the trustees of the normal schools, and the State Board of Vocational Education; it appoints a commissioner of education and four deputy commissioners. For the progress of Dartmouth College during this period *see* DARTMOUTH COLLEGE. The State College of Agriculture and the Mechanic Arts made rapid progress; the student body increased from 266 in 1910 to 818 in 1920; the teaching staff from 37 to 78; the value of the buildings from $900,000 to $1,720,000; the number of acres in the farm from 380 to 500. During the same period departments of education, forestry, home economics, industrial engineering, and poultry were added, and the laboratory equipment greatly enlarged.

*History.*—The Ninth Constitutional Convention, held in 1912, submitted to the voters 12 amendments, of which four received the necessary two-thirds vote, namely disfranchisement for treason, bribery and deliberate violation of the election laws; the substitution of plurality for majority vote in the election of governor, councillors and senators; extension of the jurisdiction of police courts; the substitution of a basis of population for that of property in the election of councillors. The Tenth Constitutional Convention was convened in the summer of 1918, ad-

journed until the close of the World War, and reconvened in Jan. 1920. It submitted to the voters seven propositions, all of which were rejected. In 1915 the office of assistant attorney-general was created, and the number of bank commissioners was reduced to three, and their term of office was made six years. The Railroad Commission became the Public Service Commission in 1911, its powers were enlarged, and the term of office of the three members was made six years. In 1913 the Fish and Game Commission was reorganized and the number of commissioners reduced from three to one. The Department of Public Instruction was reorganized in 1913 so that the superintendent holds office indefinitely; it was again reorganized in 1919. In 1913 the Department of Agriculture was reorganized with a commissioner instead of a board, and in 1915 it was further reorganized. In 1911 the name Board of Equalization was changed to Tax Commission, the members were reduced from five to three, and the tenure of office was extended from two to five years. The Bureau of Labor was reorganized in 1911, and in 1913 a Board of Arbitration and Conciliation was organized to work with it. In 1913 the License Commission was reorganized; in 1915 it was again reorganized and its name was changed to Excise Commission. The Highway Department was reorganized in 1915 with a highway commissioner at its head appointed by the governor for five years. A Department of Institutions was created in 1913 and reorganized in 1919. The state institutions were managed by seven trustees consisting of the governor and one member of the council, *ex officio*, and five appointed trustees. The institutions governed by the Department were the prison, the hospital, the sanitarium, the industrial school, and the school for feeble-minded children. During the World War the state sent into the service of the Government 22,000 persons, of whom 7,971 were called under the Selective Service Act. The remainder, more than 60% of the total, volunteered. Liberty Loans were subscribed as follows:— First, $9,894,900; Second, $15,484,400; Third, $17,282,300; Fourth, $29,346,640; total, $72,008,240, about $164 for each person in the state.

The governors after 1910 were:—Robert P. Bass (Rep.), 1911–3; Samuel D. Felker (Dem.), 1913–5; Rolland H. Spaulding (Rep.), 1915–7; Henry W. Keyes (Rep.), 1917–9; John H. Bartlett (Rep.), 1919–21; Albert O. Brown (Rep.), 1921– .

(E. J. B.)

**NEW JERSEY** (*see* 19.501).—In 1920 the pop. was 3,155,900, as against 2,537,167 in 1910, an increase of 618,733, or 24·4%, as compared with 14·9% for the United States as a whole. The density of pop., exceeded only by that of Rhode Island and Massachusetts, averaged 420 to the sq. mile in 1920. The proportion of people living in places of 2,500 or more inhabitants increased from 75·2% in 1910 to 78·7% in 1920, the urban pop. in 1920 being 2,482,289, the rural, 673,611. The growth of pop. of the ten largest cities during the decade 1910–20 is shown in the following table:—

| | 1920 | 1910 | Increase per cent |
|---|---|---|---|
| Newark | 414,524 | 347,649 | 19·2 |

*Agriculture.*—The trend toward city and industrial life is indicated by the decrease in the number of farms from 33,487 in 1910 to 29,672 in 1920, or 11·4%. Production, however, gained owing to the increased use of scientific and intensive methods, which in turn were largely due to the facilities afforded for agricultural education, as in the short and four-year courses in the State College; by the Farm Demonstration Act of the Legislature of 1913, under which farm bureaus have been organized in 18 of the 21 counties; by the Smith-Lever Act of Congress of 1914, providing for further extension of agricultural education, and the Smith-Hughes Act of Congress of 1917 with its provisions for vocational training. These and similar agencies have made a deep impression on farm life in New Jersey, especially in improved social and economic conditions.

Notable, too, are the results of agricultural research. A soil survey of the state has been made and has practically completed the classification and mapping of the soil-types. Fertility studies and the study of soil bacteriology, plant diseases and parasitic organisms, have developed methods by which production has been increased and losses diminished, especially those owing to the potato scab and to parasites of celery, sweet potatoes, peaches, apples and pears. The Japanese beetle and the gipsy-moth have recently entered the state, but the old insect foes of economic importance are coming under control. Through research in horticulture several new types of peaches, some of distinct value, have been developed, and experiments with fertilizers, insecticides and fungicides have benefited the horticultural industry.

The progress of experimentation in dairy and animal husbandry is evident in the number and quality of herds of pure-bred cattle, notably Holstein, Friesian, Jerseys, and Guernseys, in which New Jersey has become one of the leading states of the Union. Milch cows had in Jan. 1920 an average value of $128 per head, as compared with $110 in Rhode I., $107 in New York, $105 in Massachusetts and Connecticut and an average of $85.13 for the United States. While the number of dairy cows decreased in the decade 1909–19, the milk production rose from 68,000,000 gal. to 80,000,000. As New Jersey lies midway between New York and Philadelphia the demand in these great centres of population has caused the New Jersey dairies to abandon the production of manufactured dairy products in favour of market milk, the value of which in 1919 totalled $20,000,000.

Next in importance to dairying is the keeping of swine, the chief breeds being the Berkshires, for which New Jersey is noted, and the Duroc Jerseys. In poultry-farming the decade 1910–20 witnessed several important developments. Operation and management were placed on a commercial basis. The number of birds is over 3,000,000, of which one-third are in commercial plants, one-third in suburban and city back yards, and one-third in farm flocks. In 1920 poultry and eggs were produced to the value of $35,000,000.

Progress has been made also in adapting crops to soil conditions, particularly corn, alfalfa and soya beans. The acreage of alfalfa has increased from a few thousand to 30,000 acres. A system of cropping and green-manuring has been developed, which, with the use of commercial fertilizers, has improved the general fertility of the soil. Per acre average crop yields have increased during the period as follows: rye from 14½ to 18 bus., wheat from 15½ to 18½ bus., corn from 38 to 41 bus., potatoes from 105 to 130 bushels. A number of minor crops have been tested and included in the crops grown, such as sudan-grass, millet and vetch. Specialized types of farming have been largely localized in definite regions on definite soil-types; a white-potato section has been developed in the vicinities of Freehold, Bridgeton, Medford, Mount Holly and Camden; dairy sections in the northern portion of the state and elsewhere; poultry sections in the regions of Vineland, Lakewood and Tom's River. Coöperative organizations have been formed to meet the needs of these specialized sections, such as a state potato association, alfalfa association and others. The horticultural products in 1920 were valued at $50,000,000. Large plantings of apples and peaches in Burlington, Gloucester and Cumberland counties indicate the progress of commercial fruit-growing.

*Mining.*—New Jersey ranks fifteenth in the value of its mineral products and third in value per sq. mile. In the production of zinc Oklahoma alone surpasses it. The ore body of the two New Jersey zinc mines of Sussex county is unique in composition and is the largest and probably the richest of any known ore body in the world. Metallic zinc, zinc oxide and spiegeleisen are the chief products, amounting in 1918 to nearly 700,000 tons. The iron-mining industry, which from about 100 mines attained a maximum output of nearly 1,000,000 tons in 1882 and then declined, has been revived and the recent annual production has been about 400,000 tons. A few financially strong companies have expended large sums for the ore shafts, underground development and the erection of magnetic concentration plants, and a number of new ore bodies have been developed. In the mining of clays New Jersey in 1918 ranked third among the states, the raw clay production of that year being 286,474 tons. In the value of pottery products it stands second to Ohio. The total value of New Jersey's clay and clay products in 1918 was approximately $22,000,000. Brick and tile, terra-cotta, stone, cement, sand and gravel and miscellaneous items raised the value of the mineral production for 1918 to nearly $50,000,000. The state possesses in the green sand (marl) deposits vast stores of potash which, to be available for plant use, requires complicated chemical treatment. Efforts were made during the World War and after to recover the potash from these beds.

*Manufacturing.*—In variety of manufactures New Jersey surpasses any other state. It ranks sixth in the value of its annual product and second in the *per capita* value. About 17% of the population is actively engaged in manufacturing. It ranks first in the smelting and refining of copper, in the refining of oil, in the manufacture of linoleum and sewing-machines; second in the manufacture of silk, and in chemical and rubber products; third and fourth respectively in the production of electrical machinery and supplies and of toilet articles. In 1918 the capital invested in manufactures totalled $1,888,298,757; the value of stock used was $1,834,-

580,122; the selling value of goods was $2,990,939,855; total amount paid in wages $530,733,577. In the same year the average number of persons employed was 499,279; of these 377,328 were men (16 years of age or over), 115,143 were women, and 6,508 were from 14 to 16 years old. The average earnings per employee were $1,063; average number of days at work 289·06; of hours worked per day 9·25; of hours per week, 52·24.

*Education.*—The Russell Sage Foundation, after an exhaustive examination of the public school systems of the various states, ranked New Jersey in 1920 first among the states east of the Mississippi river, fourth in the whole country, and added that it was "the only state in the eastern division that has gained in relative rank during a period of 28 years, 1890–1918." An Act of the Legislature of 1911 made notable changes in school administration. The State Board of Education consisted in 1921 of eight members with increased powers of control. The Act replaced the superintendent of public schools with a commissioner of education, with enlarged powers. The report of this commissioner for 1920 gave the total enrolment of pupils as 623,284, an increase of 26,290 over 1919 and of 44,353 over 1916. The number of teachers was 18,873; of school buildings, 2,106. Over 600,000 children were furnished with books and supplies free of cost. Nearly 300,000 received manual or industrial training of some sort, and 13,000 some form of vocational training. There were 31,486 pupils in the evening schools, 40,282 in the kindergartens, 276,498 in the first four grades, 181,864 in the four higher grades, 55,243 in the high-schools as against 38,099 in 1914. The current expense for operating the schools during the year 1919–20 was $30,854,795.53, an increase over the previous year of $5,403,716.10. Of this total more than $20,000,000 was for salaries of teachers, superintendents and principals. The school moneys were derived as follows: state school fund, $250,000; appropriations by Legislature for general purposes, $696,006; appropriations from state railroad tax, $4,564,879; state school tax, $235,046; surplus revenue fund, $28,480; local appropriations, $24,155,265; other sources, $1,382,893. The school properties in 1911 were valued at $44,000,000; in 1920 at $102,000,000. The average salary paid to teachers in 1920 was $1,177.20. A third state normal school, that at Newark, was opened in 1916. Schools under private control are numerous throughout the state. The Catholic parochial schools numbered in 1919 189, with 83,524 pupils. A legislative Act of 1917 designated the state college (Rutgers) as the "State University of New Jersey." This institution had on its rolls in Jan. 1921: graduate students, 30; undergraduates, 678; college for women, 179; summer session, 559; short courses in agriculture, 149; extension courses, 589. A college for women affiliated with it was opened in Sept. 1918. Stevens Institute of Technology in 1921 had on its rolls 862 students; Princeton (*see* PRINCETON UNIVERSITY), 1920–1, 1,814 undergraduates, 149 graduates.

*Legislation.*—The general spirit of the time was clearly evident in the legislation of New Jersey during the decade 1910–20. The influence of the "Progressive" movement, reinforced by the activities of Gov. Woodrow Wilson, 1911–3, secured the enactment of several radical measures. For more than two generations New Jersey had, beyond any other state, sedulously fostered the aggregation of capital in corporate form, but this policy was reversed by the passage in 1913 of the series of Acts widely known as the "Seven Sisters," whose purpose was the elimination of the power of "trusts" to create restraint of trade, monopoly, limitation of production and price-fixing. Subsequent legislation repealed or greatly modified these laws.

The long-cherished policy of opposition to a state debt was changed in 1920, when the Legislature proposed and the people ratified an issue of bonds to the amount of $28,000,000 for the construction, as a part of the highway system, of a bridge across the Delaware and a tunnel under the Hudson river. At the same election the people approved a law to authorize an issue of bonds to the amount of $12,000,000 as a bonus to those who served in the World War. A budget system was introduced in 1916 and a central agency for the purchase of departmental supplies.

The laws governing elections were radically changed in 1911 and subsequently, by provisions extending the application of the direct primary law and providing the blanket ballot and safeguards against frauds. In 1911 also the commission form of municipal government was introduced, and by 1920 had been adopted by about 40 municipalities, including the largest cities. The Practice Act of 1912 is noteworthy as simplifying procedure in the courts. The legislation of this period further embraced the following subjects: the regulation and control of public utilities; jury reform; employers' liability; workmen's compensation; conditions and hours of labour; labour of women and children; juvenile courts; women as police officers; sanitary safety conditions; motor vehicle control; a state system of highways; inheritance and bank stock taxation; regulation of insurance; water-supply; food laws and storage of food; civil service in state and municipalities; state administration of municipal sinking funds.

The various war measures of the Legislature were in keeping with its Act of March 26 1917, 11 days before war was declared, directing the governor in aid of the nation's cause "to organize and employ any and all resources within the State." The number of men from New Jersey serving in the World War was 138,691; army, 114,534; navy and marine corps, 23,951; coast and U.S. guards, 206. According to the most recently compiled casualty statistics, 119 officers and 2,311 enlisted men lost their lives on foreign soil, while 37 officers and 856 enlisted men died in the United States and its possessions; the wounded were 7,620 (officers 219, men 7,401); prisoners 188 (officers 20, men 168). The records of the Navy Department show a total loss of 227, of whom 168 died of disease, 24 in enemy action, and 35 by accidents. In the marine corps 80 men lost their lives while serving with the U.S. Marines in France, 16 while serving in the United States and foreign stations other than the American Expeditionary Force. The subscriptions in New Jersey to the Liberty and Victory Loans were: first, $82,519,450; second, $140,209,300; third, $139,858,500; fourth, $236,826,600; Victory, $173,645,050; total $773,058,900.

*Political History.*—Woodrow Wilson was elected governor in 1910 as candidate of the Democratic party, receiving a plurality of 49,056. His success in the state campaign, and the character of his administration, attracted the attention of the whole country and led to his nomination and election to the presidency in 1912. In each of the seven presidential elections after 1892 the electoral vote of New Jersey was cast for the candidate of the Republican party except that of 1912, when Wilson, owing to the split in the Republican ranks, secured a plurality of 24,873. He lost the state to Hughes in 1916 by 57,707 plurality. In 1920 Harding, Republican, received 611,670 votes; Cox, Democrat, 258,229. In the elections for the state executive the Democratic party was successful in 1910, 1913 and 1919, the Republicans winning in 1916. The Legislature also varied in party affiliation during this period, but from 1914 the Republicans obtained the control of both Houses. In 1921, of the 21 Senators, 15 were Republicans, 6 Democrats; in the Assembly there was but one Democrat, the other 59 were Republicans, of whom two were women. In the sixty-seventh Congress of the United States both New Jersey's Senators were Republican, and of the state's 12 Representatives but one was a Democrat.

New Jersey's governors were: Woodrow Wilson 1911–3; James F. Fielder (acting), 1913; Leon R. Taylor (acting), 1914; James F. Fielder, 1914–7; Walter E. Edge, 1917–9; William H. Runyon (acting), 1919; Edward I. Edwards, 1920–

(A. Sc.)

**NEW MEXICO** (*see* 19.520).—The pop. in 1920 was 360,350 as against 327,301 in 1910, an increase of 33,049, or 10·1%, as against 67·6% in the preceding decade. The urban pop. (in places of 2,500 inhabitants or more) in 1920 was 18% of the total, as compared with 14·2% in 1910. The average number of inhabitants per sq.m. in 1920 was 2·9; in 1910 it was 2·7. The following table shows the growth of the principal cities for the decade 1910–20:—

| | 1920 | 1910 | Increase per cent |
|---|---|---|---|
| Albuquerque | 15,157 | 11,020 | 37·5 |
| Santa Fé | 7,236 | 5,072 | 42·7 |
| Roswell | 7,033 | 6,172 | 13·9 |
| Raton | 5,544 | 4,539 | 22·1 |
| Clovis | 4,904 | 3,255 | 50·7 |

*Agriculture.*—During the decade 1910–20 the number of farms decreased from 35,676 to 29,844, or 16·3%; all land in farms increased from 11,270,021 ac. to 24,409,653 ac., or 116·6%; improved land increased from 1,467,191 ac. to 1,717,224 ac., or 17%. The value of all farm property rose from $159,447,990 in 1910 to $325,185,999 in 1920. The average acreage per farm in 1920 was 817·9 ac.; in 1910 it was 315·9 ac. The average value of land per acre decreased from $8.77 in 1910 to $8.04 in 1920. Of the 29,844 farmers in 1920, 25,756 were owners, 433 managers, and 3,655 tenants. The increase in the chief agricultural products during 1909–19 is shown in the following table:—

| | | Acres | Production | Value |
|---|---|---|---|---|
| Corn | 1919 | 227,167 | 4,737,182 bus. | $7,105,781 |
| " | 1909 | 85,999 | 1,164,970 " | 984,052 |
| Oats | 1919 | 40,029 | 1,085,311 " | 1,139,580 |
| " | 1909 | 33,707 | 720,560 " | 439,306 |
| Wheat | 1919 | 135,185 | 2,437,213 " | 4,874,426 |
| " | 1909 | 32,341 | 499,799 " | 508,726 |
| Beans | 1919 | 112,419 | 850,334 " | 2,976,176 |
| " | 1909 | 20,766 | 85,795 " | 232,023 |
| Hay and forage | 1919 | 436,547 | 693,807 tons | 12,852,751 |
| " " | 1909 | 370,596 | 433,504 " | 4,493,918 |

Of live stock on farms in 1920 there were 182,686 horses, valued at $9,696,377; 20,369 mules, valued at $1,874,836; 1,237,551 beef cattle, valued at $59,580,397; 62,794 dairy cattle, valued at $3,520,903; 1,640,475 sheep, valued at $15,413,670; 87,906 swine, valued at $1,462,470. The production of wool in 1919 was estimated at 15,076,000 lb. In 1920 the number of farms irrigated was 11,390; the area irrigated was 538,377 ac., or 31·4% of the improved land in farms. The capital invested in irrigation enterprises was $18,210,412, as against $9,154,897, in 1910.

*Manufactures.*—Between 1914 and 1919 the capital invested increased from $8,984,000 to $15,226,000 or 69·5%, and the value of products from $9,320,000 to $17,857,000 or 91·6 per cent. The average capital per establishment increased from $24,000 to approximately $39,000, during the same period. The value added by manufacture in 1919 was 56·7% of total value of products as compared with 52·5% in 1914. The chief manufactures are lumber and timber products; railway-car construction; printing and publishing; and gristmill products. The following table, compiled by the U. S. Census Bureau, shows the other manufacturing statistics for the period 1914–9:—

| | 1919 | 1914 | Increase per cent |
|---|---|---|---|
| Number of establishments | 387 | 368 | 5·2 |
| Proprietors and firm members. | 336 | 325 | 3·4 |
| Salaried employees | 574 | 493 | 16·4 |
| Wage-earners, average number | 5,736 | 3,776 | 51·9 |
| Salaries | $1,027,341 | $ 577,243 | 78· |
| Wages | 6,658,462 | 2,695,448 | 147· |
| Materials, cost | 7,727,483 | 4,430,134 | 74·4 |
| Value added by manufacture. | 10,129,119 | 4,889,933 | 107·1 |

*Transportation.*—In 1918 the railway mileage of New Mexico was 3,041, excluding switches and sidings. The Atchison, Topeka & Santa Fé railway owned 1,426 m. of track, almost half of the total. The other principal railways were the El Paso & Southwestern, 741 m.; the Denver & Rio Grande, 235 m.; the Southern Pacific, 167 m.; the Chicago, Rock Island & Pacific, 152 m.; and the New Mexico Central, 115 miles. During 1917–8 about 1,600 m. of highways were improved, involving the building of 1,200 culverts and 260 bridges, at a total cost of $1,500,000. In 1912 the territorial roads commission became a state highway commission in control of the state road fund; county road boards succeeded road supervisors. Counties may issue bonds for highways and bridges.

*Mineral Products.*—The total value for 1918 was $40,631,024, as compared with $18,072,919 in 1914. The chief products were: coal, 4,023,239 tons; copper, 98,264,563 lb.; zinc, 24,050,000 lb.; lead, 10,180,000 lb.; silver, 782,421 ozs. The value of the gold production was $683,000.

*Education.*—In 1916 a movement was begun to standardize and make more uniform the high-schools. In 1917 the state, taking advantage of the Smith-Hughes Act for promoting vocational education, received from the Federal Government $15,000, which was doubled by a like appropriation from the state. For the year ending June 1 1918 the total school enrolment was 62,422, of which number 31,538 were boys and 30,884 girls. The average daily attendance was for boys 19,807 and for girls, 20,000, a total of 39,807. The total number of children, age 7 to 14, in the state was 67,947. The number of school-houses was 1,289. The average monthly salary for men teachers was $71.52 and for women $67.66. Among the laws passed by the state Legislature in 1919 was one providing for compulsory school attendance between the ages of 6 and 16; children between the ages of 14 and 16 may be excused to enter employment. A child welfare department was created at the same time and placed under the jurisdiction of the Department of Education. The university of New Mexico, at Albuquerque, had in 1920 about 400 students and 35 officers of instruction. David Spence Hill was president. The museum of New Mexico, established at Santa Fé in 1909 in the historic palace, built about 1630, of the governors of the old Spanish province, contains a remarkable collection illustrating American archaeology and a notable library of works on general linguistics. The Archaeological Institute of America maintains there a special school of American Research. In 1918 the state spent $1,266,000 on its educational institutions, comprising the university of New Mexico, at Albuquerque; the State College of Agriculture and Mechanic Arts, at State College; the Military Institute, at Roswell; the Normal University, at Las Vegas; the Normal School, at Silver City; the Spanish-American Normal School, at El Rito; the School of Mines, at Socorro; the Deaf and Dumb Asylum, at Santa Fé; and the Institute for the Blind, at Alamogordo.

*Finance.*—For the first seven years of statehood, Dec. 1 1911 to Nov. 30 1918, the aggregate state expenditures were $15,573,817 and county expenditures $34,227,143, making a total of $49,800,960. State receipts amounted to $16,520,448 and county receipts $34,235,224, making a total of $50,755,672. At the end of that period the bonded state debt was $3,385,500; county, $2,972,335; city, town and village, $3,250,000; school, $1,800,000, making a total of $11,407,835. In 1918 the total assessed valuation was $360,961,891, as compared with $72,457,454 in 1912. There were in 1918 43 national banks with capital stock totalling $2,765,000 and resources of $45,000,000; 22 state banks with capital stock totalling $2,615,980 and resources of $19,110,000.

*Legislation.*—In 1913 the state Legislature ratified the Federal income tax amendment. Other legislation included a local option law; a "white slave" law; provision for an optional commission form of government for cities, towns and villages. In 1917 a workmen's compensation law was enacted; regulations concerning examination for admission to the bar were improved; and provision made for part payment of transportation expenses of normal school students from distant parts of the state. In 1919 legislative acts included the establishment of state mounted police; a Child's Welfare Bureau; an annual franchise tax on corporations; state inheritance and income taxes; fixing the maximum rate of interest at 10%; provision for teaching of Spanish in high-schools on petition; and the establishment of night-schools for illiterates. In 1914 an amendment of the state constitution was adopted, changing the terms of state and county officers from four to two years. In 1918 an article was added prohibiting the manufacture and sale of intoxicating liquors after Oct. 1 1918 (28,732 for, 12,147 against).

*History.*—The most important historical fact concerning New Mexico during the decade 1910–20 was its admission into the Union, June 6 1912, as the 47th state. Following the Enabling Act, passed by Congress June 20 1910, the territorial governor ordered an election of delegates to frame a constitution. The election was held Sept. 6 1910; the convention, consisting of 71 Republicans and 29 Democrats, assembled Oct. 3; and the adopted constitution was approved by the people Jan. 21 1911. The vote was 31,742 for, and 13,399 against. The chief opposition came from voters who favoured the inclusion of state prohibition. Certain provisions in the constitution made amendment difficult. These were not approved by President Taft, and Congress passed a resolution that at the election of Nov. 1911 the people should decide whether amendment should be made easier. The Republicans were pledged against such change, but favoured a repeal of the section requiring as a qualification for state office ability to speak and write English without the aid of an interpreter. Although as a territory New Mexico had been Republican, the Democratic candidate for governor, William C. McDonald, was elected, receiving 31,036 votes to 28,019 for H. C. Bursom, the Republican candidate. The governor was inaugurated Jan. 15 1912. The Republicans elected a majority of members of both Houses of the Legislature, the Democrats securing all state offices, excepting those of auditor and attorney-general. Two Republicans were sent to the U.S. Senate; one Republican and one Democrat were elected to the U.S. House of Representatives. An amendment to the constitution making it easier of amendment was carried by an overwhelming vote. One of the first two U.S. Senators to be elected was Albert B. Fall, who served by re-election until 1921, when he entered the Cabinet of President Harding as Secretary of the Interior. The presidential vote in 1912 was 20,437 for Wilson, 17,733 for Taft, and 8,347 for Roosevelt; in 1916 it was 33,524 for Wilson, and 31,152 for Hughes.

In 1916 the Elephant Butte Dam, under active construction since 1910, was completed by the U.S. Reclamation Service at a cost of about $5,000,000. It is situated 12 m. W. of Engle, Sierra county. Built across canyons of the Rio Grande, it governs the entire flow of the river and is the largest storage irrigation reservoir in the world. The average width of the reservoir is 1½ m., maximum length 45 m.; the area of water surface, when full, 40,080 ac., the shore line 200 m.; the average depth 66 ft., and the maximum depth near the dam 193 ft. When full it holds 115,498,000,000 cub. ft., or 862,200,000,000 gallons. It irrigates 185,000 ac. of land, lying in New Mexico, Texas and Mexico (25,000 ac.).

About 15,000 men were inducted into service during the World War. The final allotments for the Liberty Loans, all heavily over-subscribed, were as follows: First, $1,392,850; Second, $3,860,100; Third, $5,903,300; Fourth, $5,898,100; Victory, $2,925,500.

The last territorial governor was W. J. Mills (Rep.), 1910–2. State governors were W. C. McDonald (Dem.), 1912–7; Ezequiel de Baca (Dem.), Jan. 1–Feb. 18 1917; W. E. Lindsey (Dem.), 1917–9; A. Larrazolo (Rep.), 1919–21; M. C. Mechem (Rep.), 1921–

**NEWSPAPERS** (*see* 19.544).—(1) GREAT BRITAIN.—The account of English journalism given in the earlier article brought its history practically down to the moment when in 1908 Lord Northcliffe had become chief proprietor of *The Times*. In later years the newer developments in daily and weekly journalism, which may be said to have begun with the establishment of the *Daily Mail* in 1896, were seen in extended operation. Every newspaper endeavoured to make a broader appeal than formerly in the desire to attract the ever-increasing body of readers produced by the Education Act, which wants matter served up in a fashion markedly different from that which was usual when, taken as a whole, the comparatively small newspaper-reading public was composed of educated people. As Mr. Gladstone remarked years ago, "The press, which was formerly the privilege of the educated classes, has become the patrimony of the people." Also, women had become regular readers, and, in order to increase circulation, it was necessary to cater to their tastes. The general tendency, consequently, has been to be less academic and more and more personal and "snappy." The use of the editorial "we," and all that it implies in the way of detachment, real or affected, is rapidly passing away, and the old-fashioned "leader" is going the way of all things. Most present-day readers want news, not opinions. The "tit-bits" style of presentation is apparently what is best liked by the majority, and as the majority pays the piper, proprietors for the most part let it call the tune. For instance, there have been very radical changes in parliamentary reporting. In 1909 practically every paper of importance had its own corps of reporters, but now most papers obtain their reports from a newsagency and few devote much space to them; and there is this justification for the change, that nowadays more people read the summary of parliamentary proceedings which is generally given than the full report. In nearly all London daily papers illustrations are inserted, either regularly or occasionally, and at least one paper with a very great circulation has given over its back page entirely to the reproduction of photographs of current events, except for a sprinkling of advertisements. Also, these papers usually devote a page or a column to gossipy paragraphs, fashions, and other topics specially interesting to women, and even other features likely to attract children, and so on. Further, they print serially from time to time books that have a wide interest, such as Ludendorff's *Reminiscences* and the memoirs of Mrs. Asquith and M. de Witte.

The struggle for existence of newspapers has been vastly intensified. As a result of the World War, the price of paper was very much greater, and so also the cost of printing, and the general upkeep. The salaries of the editorial staff have risen, and wages have gone up still more materially. This has been met only to a limited extent by the increase in the selling price of the newspapers—the halfpenny press has disappeared and now (1921) charges one penny, while the selling price of the former penny paper has been doubled.

The comparative statistics of British newspaper publications show the following growth between 1909 and 1920. In 1909 there were in the United Kingdom 2,322 newspapers, distributed as follows: London, 386, of which 31 were dailies; provinces, 1,365, including 125 dailies, without localized editions; Wales, 111, including 8 dailies; Scotland, 260, including 18 dailies; Ireland, 185, including 17 dailies; Isles, 15, including 4 dailies. In 1920 there were in the United Kingdom 2,293 newspapers distributed as follows: London, within the postal radius, 440, of which 25 were morning dailies and 7 evening dailies; the English and Welsh provinces, including localized issues, 1,425, of which 41 were morning and 83 evening dailies; Scotland, 235, including 9 morning and 10 evening dailies; Ireland, 179, including 10 morning and 6 evening dailies; Isles, 14, of which 5 were dailies.

The most notable events in the newspaper world during the decade 1910–20 were: (1) the rise of the cheap illustrated papers, due to the introduction of the half-tone block and improved photographic and reproduction methods; (2) the great increase in the circulation of Sunday papers; and (3) the great increase in the circulation of evening papers in London and the provinces. It is not generally realized what large quantities of evening papers are sold, and that the circulation of evening papers much exceeds the circulation of the morning papers, with the exception of the few morning papers that have national sales.

In the matter of the development of journalism as a profession or business, it is interesting to note how the principle of trade-unionism has crept in. In so far, the relations between a proprietor and his staff have materially altered. The proprietors are just as interested in their papers as ever, and keep a tight rein on the policy, a rein at least as tight as, and perhaps tighter in many cases, than a generation earlier. Then, such men as John Walter, the first Lord Burnham and Lord Glenesk were in regular touch with their editors and managers, and now such men as Viscount Northcliffe, Viscount Burnham, Viscount Rothermere, and Lord Riddell very definitely control their papers.

In other ways, however, there has come about a distinct, though not necessarily unfriendly, cleavage between the employers and the employees of all kinds, owing to the fact that the trade unions have become one of the most important factors in the newspaper trade at the present time. The owners of London daily, evening, and Sunday papers have formed the Newspaper Proprietors' Association, which deals as a body with questions in which they are jointly interested, such as labour matters, cable charges, and railway facilities. The association was represented at the Peace Conference, and acted through its representatives as a *liaison* between the British delegates and the British press. The owners of periodicals, magazines, and the trade papers are banded together under the style of the Weekly Newspapers and Periodicals Proprietors. In the provinces, the proprietors are linked up in the Newspaper Society, the Northern Federation of Newspapers, the Southern Federation of Newspapers, the Scottish Newspaper Proprietors' Association, the Irish Newspaper Society, and the Associated Irish Newspapers. Manchester has its Newspaper Federation, and Ireland its Irish Master Printers' Association. There is, further, a British Association of Trade and Technical Journals, Ltd.

The journalists, too, besides the old-established Institute of Journalists, have now another organization, the object of which is to better the position of the journalist, to secure for him a reasonable security of the tenure of his post, and to enforce minimum salaries for the different kinds of work, which minimum rate, however, varies according to the locality, London rates being distinctly higher than those in the provinces. This union keeps a very close control over its members, as is shown by a recent notice: "Members of the National Union of Journalists who accept any new position without first informing the General Secretary are liable to be expelled from the Union. This is necessary owing to the great variety of recognized local rates." There is also a Society of Woman Journalists. The British International Association of Journalists works on behalf of journalists of all countries, and has organized international press conferences; and the Empire Press Union works on behalf of the press of Great Britain, the Dominions and Colonies.

In the provinces the whole of the trades are represented by one body, called the National Printing and Kindred Trades Federation. In London each trade has its own union—the compositors, stereotypers, and so on—but they are all welded together for certain purposes in the London Printing Trades Federation. One of the most remarkable newspaper incidents of modern years was the Lancashire strike or lock-out in 1920, which resulted in the newspapers of that district suspending publication for nine days.

The newsagents have their organizations—the Federation of Wholesale Newsagents and the National Federation of Retail Newsagents. Other societies directly interested in newspapers are, on the one side, the Association of Advertisement Managers of the London and Provincial Press, Ltd., and, on the other side, the Incorporated Society of British Advertisers. In fact, the newspaper trade is most highly organized in all its branches, and, on the whole, its members are highly paid.

*London Newspapers.*—There were many changes between 1909 and 1921 in the London press. The morning daily paper, the *Standard*, which dated back to 1827, ceased to appear in 1911; in 1912 the *Morning Leader*, which was founded in 1892, was amalgamated with the *Daily News*; in 1921 the *Globe*, the oldest of the

existing evening newspapers, was absorbed by the *Pall Mall Gazette*, which last now appears as the *Pall Mall and Globe*. In Nov. 1921 the evening *Westminster Gazette* was transformed into a morning Liberal paper, with Mr. J. A. Spender still as its editor, the former green paper being changed to white.

The *Morning Post* subsequently to 1911 was edited by Mr. H. A. Gwynne (who had been editor of the *Standard* from 1905 until that date), in succession to Mr. (afterwards Maj.-Gen. Sir) Fabian Ware, who had been in charge since 1905.

Mr. George Earle Buckle (b. 1854) resigned the editorship of *The Times* in 1912, when he was replaced by Mr. Geoffrey Robinson (afterwards Dawson; b. 1874), a fellow of All Souls', Oxford, who had joined the staff a year or so before, after having been editor of the *Johannesburg Star* in S. Africa, where he had originally gone in 1901 as private secretary to Lord Milner. Mr. Dawson resigned in Feb. 1919, and was succeeded by Mr. H. Wickham Steed, who had been a foreign correspondent of the paper since 1896 and had been foreign editor since 1914. In 1920 Sir Campbell Stuart, K.B.E., who had been second-in-command to Viscount Northcliffe in the Department of Enemy Propaganda, was appointed deputy-chairman and chief manager. Death claimed two valued contributors to the paper: Sir Donald Mackenzie Wallace (d. 1919), who, after acting as correspondent in Russia, Turkey and Egypt, was director of the foreign department from 1891 to 1899; and James David Bourchier, who had represented the paper in the Near East. *The Times* now publishes weekly an *Imperial and Foreign Trade Supplement*, and a similar publication monthly in Spanish. It has brought out "*The Times* History of the War," a new *Times Atlas*, and "*The Times* Documentary History of the War."

In 1912 the *Morning Leader*, founded in 1902, was incorporated with the *Daily News* (which owns the *Star*), and various changes were made in the board of directors. Mr. A. G. Gardiner retained the editorship which he had held since 1902, but he resigned in Sept. 1919. His successor was Mr. Stuart Hodgson, who had been assistant-editor of the *Morning Leader* and had transferred his services to the *Daily News*.

The *Daily Telegraph* suffered fewer changes than most London papers. After the death of the first Lord Burnham (1833–1916), his son, the second Baron and first Viscount, who had assisted his father in the general control of the paper, assumed complete control. The veteran managing editor, Mr. John Merry le Sage (b. 1837), was knighted in 1918.

The *Daily Chronicle*, together with *Lloyd's Sunday News*, was sold in 1918 to a syndicate, the United Newspapers (1918) Ltd., headed by Sir Henry Dalziel, Bart. The change in proprietorship caused no change in the policy of the paper, but its attitude was broadened so as to appeal to all sections of the Liberal party. On the sale of the paper, Mr. Robert Donald retired from the editorship, and was succeeded by Mr. Ernest Alfred Perris, who had been long associated with the paper. *Lloyd's Sunday News* in 1919 came under the editorship of Mr. W. S. Robinson.

In the case of the *Morning Advertiser*, Mr. H. C. Byssche succeeded to the editorship in 1911.

In 1919 a controlling interest was purchased by Messrs. William E. & J. Gomer Berry in the *Daily Graphic*, the weekly *Graphic* (editor, Mr. J. M. Bulloch), and the *Bystander* (editor, Mr. A. Spenser Allberry). The same firm in 1915 acquired the control of the *Sunday Times* (editor, Mr. Leonard Rees).

The *Daily Express*, founded in 1900 by a company of which Mr. (afterwards Sir Arthur) Pearson was chairman, was taken over in 1913 by a new company in which the principal shareholders were Lord Beaverbrook, Lord Faringdon, and Mr. R. D. Blumenfeld, who had been editor since 1904.

The *Daily Mirror*, founded by Viscount Northcliffe in 1903, was purchased 11 years later by his brother, Viscount Rothermere, who on March 14 1915 started the *Sunday Pictorial*, which marked a new departure in journalism, being the first Sunday picture-paper. Viscount Rothermere also obtained control of the *Leeds Mercury*, the *Glasgow Daily Mail*, the *Glasgow Sunday Mail* and the *Glasgow Weekly Record*.

Messrs. E. Hulton & Co., Ltd., of which the chairman was Sir Edward Hulton and the managing director Mr. James Heddle, was the first firm from the provinces to compete with the London daily illustrated newspapers through the *Daily Sketch*. In 1915 the same firm founded the *Illustrated Sunday Herald*. It owns in the provinces the *Daily Despatch* and the daily *Sporting Chronicle*, and two Sunday papers, the *Sunday Chronicle* and the *Empire News* (formerly the *Umpire*). This firm also acquired the London *Evening Standard*, which was until Jan. 1920 edited by Mr. A. H. Mann, who then resigned to take up the editorship of the *Yorkshire Post*. Mr. Heddle subsequently acted as editor-in-chief.

The *Pall Mall Gazette* was sold in 1915 by Major (afterwards the second Lord) Astor to Sir Davidson Dalziel, from whom Sir Henry Dalziel purchased it two years later. In 1920 the last proprietor transferred the major part of his shares to the Hon. Morton Weir, son of Lord Inverforth. In Feb. 1921 the *Globe* was amalgamated with it, and later in the year the proprietorship passed into the hands of Sir John Leigh, Bart. In 1912 Mr. Higginbottom, who had been editor since 1909, was succeeded by Mr. J. L. Garvin, and in 1915 by Mr. D. M. Sutherland.

As regards Sunday papers published in London, reference has already been made to the *Sunday Times*, the *Sunday Pictorial*, and *Illustrated Sunday Herald*. The *Observer* continued to be edited by Mr. J. L. Garvin, but in 1911 it was acquired by the first Lord Astor, and it passed on his death to his son. The *Sunday Express* was founded by Lord Beaverbrook, a principal shareholder in the *Daily Express*, and the first number appeared on Dec. 29 1918. It was edited by Capt. Bird until March 1920, when he was replaced by Mr. James Douglas, formerly editor of the *Star*. The *National News* was founded in 1917, and purchased by Odham's Press, Ltd. In 1921 it was transferred to a syndicate, Sunday Publications, Ltd., the head of which was Mr. Horatio Bottomley, M.P., the founder and editor of *John Bull*, who also founded the *Sunday Illustrated* in July 1921.

The *Sunday Evening Telegram*, the only Sunday evening paper, was started during the war by Sir Henry Dalziel, and purchased by Odham's Press, Ltd., in Oct. 1919. In 1921 it was transferred to the Sunday Publications, Ltd. These last two papers were edited, under Mr. Bottomley, by G. C. H. Read.

During recent years a Labour press has come into prominence. The *Daily Herald* was started in 1911 by Mr. T. E. Naylor and members of the London Society of Compositors, who were then on strike and set up their own paper as a means of getting their case stated in a way in which they believed they could not get it stated in the general press. Its total capital was about £2,000. When the strike was over it attempted to develop itself from a strike sheet into an ordinary daily paper, with a strong political programme of what was then the extreme Left. Presently Messrs. George Lansbury, Ben Tillett, and others became directors, but it never secured a very large circulation, and in the autumn of 1914 it was changed into a weekly paper, under the editorship of Mr. George Lansbury. It was revived as a daily paper in March 1919, Mr. Lansbury remaining editor, Mr. Gerald Gould, well known as a poet, being associate-editor. Considerable sums of money were raised as debentures from the trade-union movement, and a trade-union committee, a purely advisory body, was appointed. In 1920 an outcry concerning the proposed acceptance of money from a Bolshevik source resulted in the retirement from the directorate of Mr. Francis Meynell. The *Daily Citizen* appeared in Nov. 1912, and continued until June 1915, when it ceased publication for financial reasons. Mr. Frank Dilnot was the editor, and there was a controlling board, on which were Messrs. Arthur Henderson, Ramsay MacDonald, W. C. Anderson and other official representatives of the Labour party, of which it was the official organ. The paper was financed by the trade unions.

There have been numerous weekly and monthly Labour papers, amongst which may be mentioned the *Labour Leader*, the official organ of the Independent Labour party, and the *Communist* (edited by Mr. Francis Meynell), the official organ of the new Communist party of Great Britain.

In the weekly periodicals there have been comparatively few changes. The *Saturday Review* changed hands in 1917, when Mr. A. A. Baumann (at one time a London M.P.) succeeded Mr. Harold Hodge as editor, and directed it until the spring of 1921, when he retired. The paper was then purchased by Sir Edward Mackay Edgar, and Mr. Sidney Brooks was appointed editor, but later in the year various improvements were made and Mr. Filson Young became editor, with Mr. Hartley Withers (previously editor of the *Economist*) as financial editor. The old-established *Athenaeum* ceased to appear as a separate publication in 1921, when it was amalgamated with *The Nation*. Newer papers that have appeared are the *New Witness*, founded in 1912, and edited by Mr. Cecil E. Chesterton until his death in 1919, when his brother, Mr. Gilbert Keith Chesterton, took his place. The *Review of the Foreign Press* is the continuation as a private enterprise of a paper founded and issued by the General Staff of the War Office during the war. It was still edited in 1921 by Capt. W. E. Barber, who was mainly responsible for it since its inception. Among illustrated weekly papers *Black and White* has ceased to appear; Mr. Clement Shorter in 1921 still edited the *Sphere*, but he had retired from the editorial chair of the *Tatler*, where he was succeeded by Mr. Huskisson. Several women's papers have appeared, including *Vogue*, *Femina* (edited by Lady Diana Cooper), and "*The Times* Woman's Supplement." In 1921 the last-named and the *Lady's Pictorial* were incorporated with *Eve* (published by the Sphere and Tatler, Ltd.), edited by Mr. Huskisson. The monthly *Englishwoman* ceased to appear in 1921. The improvement in the illustrations in the higher type of weekly has been very marked. Several of these papers now present illustrations in colour.

The industrial press has vastly increased in numbers, especially publications concerning the motor, wireless, cinematograph, and aerial trades.

(2) IRELAND.—In Dublin the *Irish Times*, with the *Evening Irish Times* and its subsidiary publications show no special changes as Unionist organs since 1907, when Mr. W. Algernon Locker, the editor, resigned and Mr. J. E. Healy was appointed editor. The *Daily Express* and the *Evening Mail*, on the death of the proprietor, Lord Ardilaun, were sold to Mr. H. L. Tivy of Cork in Feb. 1915, and Mr. H. S. Doig continued to act as editor until 1919, when he went to the management department of the *Freeman's Journal*.

Mr. Yeates was in 1921 acting editor. The *Freeman's Journal*, the *Evening Telegraph*, and associated publications have had a chequered history. Before the Easter rebellion of 1916 they were carried on as the official Nationalist newspapers under the direction of Mr. Thomas Sexton, ex-M.P. During the rebellion the offices in Princes' Street were destroyed by fire together with the entire plant and machinery. Until Feb. 1917 the papers were produced for the company by Messrs. Cahill, printers. New offices were then opened in Townsend Street, under a reconstructed board of directors. In Oct. 1919 the debenture-holders of the *Freeman's Journal* foreclosed, and the papers were put up for sale and purchased by Messrs. Martin Fitzgerald and Hamilton Edwards, Mr. P. J. Hooper, who had been appointed in 1916, remaining editor. On the disappearance of the Redmondite Nationalists at the general election of Dec. 1918, the *Freeman's Journal* became frankly Sinn Fein. The *Irish Independent*, the *Evening Herald*, and associated newspapers remained in the possession of the family of their founder, Mr. William Martin Murphy (d. June 1919), under the editorship of Mr. Timothy Harrington. Before the election of Dec. 1918 they were Independent Nationalist in politics, and after Dec. 1918 they became Sinn Fein. A few days after the attack on the Lord Lieutenant, Viscount French, between Ashtown station and the Phoenix Park, in Dec. 1919, a party of some 50 men, armed and provided with crowbars and hammers, held up the office and smashed the machinery, doing damage for which £35,000 compensation was afterwards awarded to the proprietors, to be levied on the city of Dublin. The publication of the newspapers was not seriously interfered with.

Before the rebellion in Easter week, 1916, the Sinn Fein doctrines had no direct representation in the daily press of Ireland, and it was not until the Nationalist party was swept out of existence in the Dec. 1918 election that the policy was advocated and supported by daily newspapers in Dublin, Cork and Belfast. The best literary work of Sinn Fein was done in the monthly magazines, such as the *New Ireland Review;* but there was a host of small weekly papers published in Dublin (many of which were suppressed by the authorities only to appear in a few weeks under new names), and through these both sections of the party—Liberal and Labour—reached their supporters and carried on an active propaganda.

The following is a fairly full, but by no means complete, list of weekly Sinn Fein organs, which appeared before and after the Easter rebellion of 1916: *The Leader* (Mr. Arthur Griffith); *Young Ireland* (Mr. Arthur Griffith); *Watchword of Labour* (Liberty Hall), defunct; *Nationality* (successor to *Sinn Fein;* Mr. Arthur Griffith, June 1915 to March 18 1916); *Nationality*, Feb. 17 1917 to 1921; *Phoenix*, published in Kilkenny from Dec. 9 1916 to 1917; *Young Ireland* (Young Republican's literary paper), April 21 1917 to 1921; *Irish Nation*, June 24 1916 to March 1917; *Irish Opinion* (Larkinite Labour), June 19 1916 to April 1917; *Irish Opinion* (new series), Dec. 1917 to 1920; *Irish Opinion, the Voice of Labour*, Feb. 1918 to 1920; *Irishman* (Herbert Pim's paper), Jan. 1916 to 1920; *Irish World* and *Industrial Advocate* (Labour), Sept. 17 1918 to Dec. 1920; *New Ireland* (literary moderate Irish National), May 15 1915 to Dec. 1920; *Irish Citizen* (Mrs. Sheehy-Skeffington's paper), 1912; *Ireland* (Mr. Arthur Griffith), Oct. 16 1914 to Dec. 4 1914; *Liberator* (Independent Labour), Aug. to Nov. 1913; *Irish Freedom* (Mr. Dalton's Labour paper), Nov. 1910 to Dec. 1914; *Irish Looker* (Larkinite), May 27 1911 to Oct. 1914; *Toiler* (anti-Larkin), Oct. 1913 to Dec. 1914; *Dialogues of the Day* (Sheehy-Skeffington), July to Sept. 1906; *Honesty* (scurrilous), Oct. 16 1915 to April 22 1916; *Hibernian*, Nov. 6 1915 to April 22 1916; *Worker's Republic* (Larkinite), May 29 1915 to April 22 1916; *Gael* (Mr. Walker of Liffey Street), Jan. 29 to March 18 1916; *Scissors and Paste* (Mr. Arthur Griffith), Dec. 1914 to Feb. 1915; *Gaelic Athlete* (Mr. Walker of Liffey Street), Jan. 1912 to April 15 1916; *Spark*, Feb. 7 1915 to April 16 1916; *Searchlight* (anti-Larkinite), 1915-6; and *Fianna*, 1915 to Jan. 1916.

In Belfast, the *Belfast News Letter* remained the leading Unionist organ in Ulster, and was still in 1921 owned by the Henderson family and edited by Mr. W. G. Anderson. The *Belfast Evening Telegraph* and its subsidiary publications remained Democratic Unionist, under the direction of Mr. R. H. H. Baird and the editorship of Mr. W. Stewart. The only changes are in the case of the *Northern Whig*, also Unionist in its politics and catering for the support of the mercantile element. The interest in the paper formerly held by Mr. Kerr Smiley was acquired by the Rt. Hon. Samuel Cunningham and his brother, Mr. Josias Cunningham. The editorship was in 1921 in the hands of Mr. R. J. Lynn as managing director. The evening *Ulster Echo* was merged in the *Witness*, the weekly organ of the Presbyterian Church, published by the Belfast Steam Printing Co., Ltd. The daily *Irish News* was still in 1921 Constitutional Nationalist, a supporter of the old Irish Nationalist party and of Mr. Joseph Devlin. It was in 1921 the only daily paper in Ireland flying the old Nationalist flag.

In Cork, the proprietorship of the Unionist *Cork Constitution* remained as before; and it was edited in 1921, in succession to the late Mr. W. J. Ludgate, by Mr. J. J. Sullivan. It was owned by the same company, of which Mr. H. L. Tivy is managing director, as the Dublin papers, the *Daily Express* and the *Evening Mail*. The *Cork Examiner* and the *Cork Evening Echo* were still in 1921 owned by the Crosbie family. In 1912 the editor, Mr. Michael B. O'Neill, died and was succeeded by Mr. John C. Healy. The *Cork Examiner*, after the election of 1918, became a moderate Sinn Fein organ. In Dec. 1919 it published a denunciation of murder and outrage by the Roman Catholic bishop, but it refused to insert a reply from the leaders of militant Sinn Fein. On the night of Dec. 24 the office was invaded by armed men who put most of the printing and typesetting machinery out of commission. The *Cork Examiner* did not stop publication, but the *Cork Echo* was reduced to one edition a day for several weeks and the weekly *Cork Examiner* stopped for one week. The proprietors, Messrs. Crosbie & Co., Ltd., were awarded £14,970 for malicious damage.

The following Dublin papers were published during the rebellion of Easter 1916:—

April 24 1916—*Irish Times*, *Freeman's Journal*, *Express* and *Independent*.
April 25 1916—*Irish Times* and *Independent*.
April 26 1916—*Irish Times* only.
April 27 1916—*Irish Times* only
April 28 1916—No paper.
April 29 1916—No paper.
April 30 1916—Sunday.
May 1 1916—*Irish Times* only.
May 2 1916—*Irish Times* only.
May 3 1916—*Irish Times* and *Express*.
May 4 1916—*Irish Times*, *Express* and *Independent*.
May 5 1916—*Irish Times*, *Express*, *Independent* and *Freeman's Journal*.

*The Press and the War.*—The effect of the World War on the press in all countries was tremendous, though perhaps in Great Britain it was felt less than in any other of the belligerent nations. Proprietors, like everyone else, were alarmed, not knowing what might happen, and in some cases as a precautionary measure staffs were reduced to a minimum. Economy in working expenses was essential, for it could be prophesied with certainty that if the war lasted for any considerable time paper would become scarce, and the scarcity would result in a very heavy rise of the cost. When this happened newspapers reduced their size, and presently, perforce, raised the selling price. The halfpenny press entirely disappeared. There was, naturally, a great outbreak of "propaganda" in the press. In neutral countries the papers had a difficult course to steer, for they had to stand for the war aims of their country, and were wooed by propagandists on either side. Some of the belligerents went so far in their efforts to secure public opinion as to purchase existing organs or to found new ones. For instance, an interesting chapter could be written on the German activities in this connexion, which were especially rampant in Holland and the Dutch Indies, Spain and the S. American republics. In the belligerent countries, proprietors and editors were confronted with a different, but equally difficult, task. They, for the most part, realized that it was their duty—and on the whole admirably they did it—to keep up the spirit of the people at home and to discourage the enemy. As a rule, British proprietors and editors acted with great discretion and did invaluable service in many ways, putting their duty to their country before their own interests. In the early days of the war the Newspaper Proprietors' Association acted as a medium between the Government and the press. Presently a very important body was formed by this association called the "Newspaper Conference," which included every newspaper interest in the United Kingdom. Of this Viscount Burnham and Lord Riddell, both of whom did most admirable work during the war in connexion with the press, were president and vice-president respectively. The conference met week by week and carried on the whole of the negotiations between the Government and the press. Its sphere of usefulness was presently extended. It is well worth while to note that during the whole period of the war the British press was represented by a voluntary organization, which rendered most valuable and important services to the country. This was the first time that the whole press acted together, and its unanimity, when the diverse interests and opinions are considered, was remarkable. The "Newspaper Conference" was, of course, an emergency measure, and dissolved when the war was over.

In the British Isles, as in other countries, an Official Press Bureau was established (*see* CENSORSHIP). The regulations regarding the press defined what might not be published. It

was open to any paper to publish what it thought fit, subject to liability to prosecution. The Press Bureau had no power to prevent publication. It issued news; it censored cablegrams and certain telegrams; it would read articles submitted to it and approve them for publication or refuse to give sanction. The effective steps taken by the Government to ensure accuracy in the press and the non-publication of dangerous matter were (1) the regulations, (2) the Press Bureau, and (3) the censors at the front. The main object of the regulations was to prevent information unwittingly being given to the enemy; a secondary purpose was to prevent inaccurate information being given to the public at home. In these matters the press certainly required guidance. No journalist, however able, could from his chair in Fleet Street form an accurate judgment of the value of, say, a certain action in Flanders or France or on the other fronts, which might or might not be a part of a concerted plan or even a feint. The printing of an apparently harmless piece of news might be of the greatest value in one way or another to the enemy, who studied the press of all countries with the greatest care.

Some newspapers printed statements or articles that were indiscretions, and some few papers and a journalist here and there were prosecuted. It was in the nature of an anomaly that the power of prosecutions rested, not with the directors of the Press Bureau, but with the director of Public Prosecutions. All that the directors of the Press Bureau could do, as, indeed, any citizen could, was to call the attention of the director of Public Prosecutions to an apparent breach of a regulation. A detailed account of the Bureau appeared in 1920, under the title of *The Press in War Time*, written by the late Sir Edward Cook, who, during the greater part of its existence, was a co-director with Sir Frank Swettenham. Immediately on the cessation of hostilities the Bureau ceased to operate.

*War Correspondents.*—At the beginning of hostilities the British military authorities would not allow newspaper correspondents in the war-zone, but they appointed an official "Eye-witness," whose report was furnished to the press. Owing to the representations of Lord Riddell, who was supported by Viscount Northcliffe and Viscount Burnham, Lord Kitchener, then Secretary of State for War, consented to allow six press correspondents to be accredited to G.H.Q. in France during the first week in May 1915. The original intention was that they were only to be there for a limited period, but, as a matter of fact, they remained until the Armistice. The reports of the correspondents were, of course, subject to censorship, and, though mistakes were made by the military censors, it is, as Lord Riddell has said, surprising that the system worked as well as it did, considering that the work was done by people without any previous experience and without any established principles to guide them. In France the supervision was especially strict. The correspondents were entirely in the hands of officers delegated for the purpose, who arranged everything for them, sending them in cars, always accompanied by a staff officer. Facilities on the other fronts were more easily obtained. On the Italian front, for instance, the accredited correspondents had cars, and went where they chose, without press officers in attendance. Everyone wore officer's uniform, with Sam Browne belt, and without rank badges, but with an ornamental "C" on the service cap. The principal war correspondents at the British front in France were Sir H. Perry Robinson and Sir W. Beach Thomas (*Times* and *Daily Mail*), Sir Philip Gibbs (*Daily Chronicle*), Sir Percival Phillips (*Daily Express*), and Sir Herbert Russell (Reuter's Agency). These gentlemen received the honour of knighthood for their services at the front. The above were known as "The Big Five," and were there most of the time, whereas the other papers had representatives there only occasionally, such as Messrs. H. W. Nevinson and H. M. Tomlinson. Of the French front in France were Mr. Gerald Campbell (*Times* and *Daily Mail*), Mr. H. Warner Allen (*Morning Post*), Mr. Martin H. Donohoe and the late Mr. G. H. Perris (*Daily Chronicle*), and Mr. Lester Lawrence (Reuter's Agency). On the Italian front was Mr. J. M. N. Jeffries (*Times* and *Daily Mail*), Mr. H. Warner Allen (*Morning Post*), Mr. Percival Gibbon (*Daily Chronicle*), Mr. G. Ward Price (Newspaper Press Association), Mr. E. H. Lacon Watson (Reuter's Agency), and Mr. Julius Price (Central News Agency). Other war correspondents were Mr. Ashmead-Bartlett, Mr. W. T. Massey, Mr. Prevost Battersby and Mr. Guy Beringer.

(3) FRANCE.—In recent years the French press, though its technical advance has in certain respects been comparatively small, its printing being on the whole inferior to English, and photographic reproduction having not made such improvement as in England and the United States, has shown a remarkable statistical progress. By the end of 1916 there were in France 3,780 newspapers, as compared with 1,800 40 years previously. Of these, four, namely the *Petit Parisien* (about 2,000,000), the *Matin* (1,870,000), the *Journal* (1,400,000), and the *Petit Journal* (1,050,000), reached, by the end of 1920, the exceptionally large circulation of over one million copies daily—a figure which one or two other papers, such as the *Echo de Paris* (850,000), nearly approached.

In 1910 the pioneer illustrated daily *Excelsior* was founded, but although well produced it did not attain the popularity of similar papers in England, its circulation at the end of 1920 being 200,000. Other leading papers established between 1910 and the beginning of the World War were: *L'Homme Libre* (1913), established as the personal paper of Georges Clemenceau; *La Bataille Syndicaliste* (1910), the Syndicalist daily; *Le Bonnet Rouge* (1913), also an extreme Socialist paper; and *Paris Midi* (1912), a paper which quickly obtained a large boulevard circulation.

The part played by French journalism during the World War forms a very interesting story. The opening of hostilities naturally created very great difficulties. Before a shot was fired the *Humanité* lost its director, Jean Jaurès, assassinated on Aug. 1, and in the Paris press in general for the first two weeks the utmost confusion prevailed. Several newspapers suspended publication. The general mobilization robbed them of their staffs, and the German threat to Paris and the measures for evacuation which were taken added to the difficulties, although the *Temps*, it may be noted, succeeded in moving its entire production to Bordeaux. It was only towards the end of 1914 that the position could be in any degree reëstablished. In 1915 publication went on practically unhindered, but from 1916 onwards the growing shortage of paper and the scarcity of metal for printing-presses resulted in numerous ministerial decrees curtailing the size of papers and fixing prices. All this added to the great difficulties under which newspaper production went on. Nevertheless, on the journalistic side the traditions of French writing were brilliantly maintained by several well-known writers. (*See* A. de Chambure, *Quelques Guides de l'Opinion en France pendant la Grande Guerre.*) Such outstanding writers as Maurice Barrès and the military critic, Marcel Hutin, in the *Echo de Paris;* Charles Maurras and Léon Daudet in the *Action Française;* the military critic, formerly dramatic critic, Henri Bidou, in the *Journal des Débats;* Auguste Gauvain in the *Journal des Débats;* Joseph Reinach (d. April 1921), writing over the signature "Polybe" in *Figaro*, all accommodating their party views to the *union sacrée*, guided French opinion daily on the political and military situation. Gustave Hervé, preacher of the class war, became a fervent patriot, and the title of his paper was changed from *La Guerre Sociale* to *La Victoire*. Georges Clemenceau, early in difficulties with the censorship on account of his outspokenness and his attacks on the Government's preparations for the war, changed the title of his paper to *L'Homme Enchaîné*, from which it was re-transformed to *L'Homme Libre* on his succession to the presidency of the Council.

What party activity there was in France as regards the press during the war centred round the extreme socialist papers and the person of M. Caillaux. In June 1917 this politician, or a number of persons favourable to his policy (the *Ligue Républicaine*) founded a daily paper, *Le Pays*, with the object of

furthering his ideas. Its editor was Dubarry, formerly of the *Bataille*, and in general the paper stood far to the Left. The radicalism and pacificism of the *Bonnet Rouge*, with which M. Caillaux' name had also been associated, were even more pronounced, and a series of sensational revelations was followed by a press campaign by papers of the Right, the burden of whose charges was that the paper was in German pay, which ended with the death in prison, in Aug. 1917, of the editor, Almeyréda, a former anarchist. Equally sensational revelations were made concerning the alleged German attempt during the war to buy *Le Journal* from the French senator, Charles Humbert, who acquired control in 1915 and acted as economic and financial editor until Dec. 1917. This scandal ultimately ended in the execution of the principal German agent in the affair, Bolo Pasha.

Apart from the papers mentioned the principal French newspapers founded during the war were the *Journal du Peuple*, a weekly paper from Feb. 1916 to Jan. 1917, when it became a daily; *Le Populaire du Centre*, a weekly published at Limoges, turned into a daily in April 1918, under the editorship of the Socialist leader, Jean Longuet. Both of these papers represented the minority Socialists, that is to say, the Zimmerwaldian or anti-Nationalist view. The patriotic Socialist group founded *La France Libre* in 1918; and in Sept. of that year there was established the extreme Nationalist *Démocratie Nouvelle*, a paper which distinguished itself for its violent anti-German campaign and advocacy of further occupation of German territory in 1920 and 1921.

Among French reviews the *Revue des Deux Mondes*, the *Mercure de France* (monthly instead of fortnightly), the *Revue Hebdomadaire* and *Le Correspondant* appeared throughout the war. The important literary review *Nouvelle Revue Française*, in which works of leading writers such as Paul Claudel first appeared, was forced to suspend publication, but reappeared after the establishment of peace. In 1920 was established the Nationalist review *La Revue Universelle*, and in 1921 *La Revue de France*.

(4) GERMANY.—The practice which Bismarck began of maintaining close relations with certain German papers and using them to further his policy was continued under Caprivi, who even extended it, since, although Bismarck confined his attention to papers of the Right, his successor on occasion used the Democratic papers. It is true that, apart from the official *Reichsanzeiger* (corresponding to the *London Gazette*), the *Norddeutsche Allgemeine Zeitung* was the only openly acknowledged governmental paper, but numerous other papers were constantly to be found expressing Government policy in their columns. This was brought about, when the occasion demanded, by the supply of material for articles from the particular Government department concerned. The Foreign Office, although playing by far the most important part in this inspiration of the press, was not by any means the only Government department with a newspaper side to its organization.

This system, by which all leading departments of State were kept in touch with the press, was greatly extended after the outbreak of the World War. The institution of the censorship and the penalties which attended the infraction of the regulations gave the Government very wide negative powers, and, in addition, positive work with the press was very much more thoroughly undertaken. The Government press organization was centralized in the *Kriegspresseamt*, and there presided over it until 1916 Herr Otto Hamann (see his reminiscences, *Der Neue Kurs* and *Zur Vorgeschichte des Weltkrieges*), who had served in a similar capacity under Bismarck and Caprivi. It was the function of this central office not only to control the working of the censorship, but also to supply material for articles, give the "directives" to the German newspaper press as a whole, and ensure, so far as seemed desirable, the uniformity of treatment of all current political, military, naval and economic questions. The party political sympathies of individual papers were, as a rule, not interfered with, and throughout the war such a paper as the *Berliner Tageblatt*, for example, found opportunity of expressing views on such questions as the annexation of Belgium, which appeared to be opposed to the policy of the General Staff, and in any case in violent disagreement with the papers of the Right. Certain individual reviews, also, such as Maximilian Harden's *Zukunft*, took—and at times seemed deliberately to be allowed to take—views which might have seemed almost subversive of the Government's policy. But on the whole a certain general discipline was maintained practically until the end of the war. (For a full account of the way in which the system worked, see *Wie wir belogen wurden*, by Dr. Kurt Mühsam.)

There was increasing complaint against the censorship and governmental control generally in the Radical and Socialist papers, but the majority of the press accepted the restraints patiently, and several, as, for example, the *Hamburger Fremdenblatt*, of which an edition in numerous languages was produced for propaganda purposes, lent themselves or their correspondents readily to that elaborate German propaganda organization during the war, whose ramifications were to be found in every country.

As might be expected, the lines of party divisions in the press were not so sharp during the war as before, but they were by no means obliterated. The interests of the Conservatives were principally represented by the *Deutsche Tageszeitung* (Berlin), with its preoccupation with the East and the claims of the German landowning classes, and the *Neue Preussische Zeitung* (or *Kreuz Zeitung*, Berlin). The chief Free Conservative paper was *Die Post*. Non-party Nationalism and Annexationism were voiced by the *Tägliche Rundschau* (Berlin); the annexation policy was also advocated, for obvious reasons, by the *Rheinisch-Westphälische Zeitung*, which in party politics is National Liberal. Other National Liberal organs were: the *Kölnische Zeitung*—the most important of them all, the *Leipziger Neueste Nachrichten*, *Hamburger Nachrichten*, *Berliner Neueste Nachrichten*, and *Düsseldorfer Neueste Nachrichten*. Among newspapers with no particular party axe to grind, although mainly reactionary and jingo in foreign politics, were the *Deutsche Zeitung* and the *Lokal-Anzeiger* (Berlin), which has a second daily edition published under the title, *Der Tag*, chiefly noteworthy for its sensational news stories and the open platform it provided for the expression of all kinds of opinions; other papers of the Jewish Ullstein group were the *Berliner Morgenpost*, *Berliner Zeitung am Mittag* and the *Vossische Zeitung*. This last, under the foreign editorship of Georg Bernhard, chiefly distinguished itself by its advocacy of the so-called "*Kontinentalpolitik*," that is, the formation of a continental *bloc*, under German leadership, against Great Britain and the United States.

During the war, and afterwards, the Centre party continued to be represented principally by *Germania* (Berlin) and the *Kölnische Volkszeitung*, and by the *Bayrische Kurier* (Munich) in Bavaria. The *Frankfurter Zeitung* and the *Berliner Tageblatt* held their place as the two chief Radical papers, the former maintaining its technical excellence, the latter continuing under the editorship of Theodor Wolff. In both Jewish influences remained predominant. The Social Democratic press shared in the difficulties and dissensions of the Social Democratic party during the war. *Vorwärts* was suppressed for a short time by the censorship, but was later allowed to reappear conditionally. When the divisions between the majority and minority increased, the staff of the paper sided with the latter, and it was only after a struggle that the majority succeeded in recapturing the paper for their views. At the end of the war, the division in the ranks not having been closed up, the minority or Independents founded *Die Freiheit*, while their members still further to the Left—later to issue as the Communist party—established *Die Rote Fahne*. Other after-the-war changes worth noting were the disappearance of the *Norddeutsche Allgemeine Zeitung*, which reappeared as a non-official paper entitled *Deutsche Allgemeine Zeitung*, later to be drawn, with several other papers, into the orbit of the industrialist magnate, Hugo Stinnes.

The chief German reviews at the end of 1920 were: the *Preussische Jahrbücher* (from the editorial chair of which Dr. Hans Delbrück retired in 1920), the *Neue Rundschau*—predominantly literary, but with occasional important political articles, the Conservative *Deutsche Politik* and *Grenzboten*, the Democratic *Demokratisches Deutschland*, the Radical *Hilfe* (whose editor, Friedrich Naumann, died during 1920), the Socialist *Neue Zeit* and the Nationalist-Socialist *Sozialistische Monatshefte* and *Die Glocke*.

A very considerable number of German newspapers were produced by the German armies on all fronts during the war, of which the best known was the *Liller Kriegszeitung*; the *Gazette des Ardennes* was a German propagandist newspaper issued for the population in the occupied French districts. A complete hand-list of German newspapers, with particulars of place, date of publication and so forth, was issued by the *Kriegspresseamt* in 1917 under the title *Handbuch Deutscher Zeitungen*, edited by Oskar Michel, a supplement to which appeared in 1918. For the Socialist press reference may be made to Mr. Edwyn Bevan's book, *German Socialism during the War* (1919).

(5) ITALY.—From 1911 onwards the press in Italy increased largely in numbers and influence. In 1917 there were 807 political newspapers, of which 119 were dailies. Most of these were, it is true, chiefly of local importance and not read widely

outside the city in which they were published, as, for example, *Il Lavaro* in Genoa, *Il Mattino* in Naples, *La Nazione* in Florence, and *Il Reste del Carlino* in Bologna. It is further true that, on the whole, the *Corriere della Sera*, which had by 1917 increased its circulation to 600,000 copies, remained the only universally read paper in Italy. Of late years, and in particular during the World War, the provincial character of a large part of the Italian press, arising from the fact that Italy's unification was of so recent a date, certainly tended to diminish. Certain newspapers, well established in their own cities, attempted to extend their distribution, as, for example, the *Giornale d'Italia* and *Messaggero* of Rome, both of which issued South Italian editions, while at the same time new papers were founded and took their place in the ranks of those journals most entitled to represent the various elements of Italian public opinion.

Shortly after the beginning of the war, for example, the *Idea Nazionale*, which was established in 1911 as the weekly organ of the Nationalist party, was turned into a daily, and later became the principal advocate in the press of the far-reaching claims on the Adriatic and elsewhere, associated with Gabriele d'Annunzio. The opposition of the official Italian Socialist party to participation in the war led also, at the end of 1914, to the foundation of *Il Popolo d'Italia*, which played a prominent part in the Inter-Conventionist campaign in 1915. Two other daily papers established during the war are *Il Tempo* and *L'Epoca*, both published in Rome.

The classification of the Italian press according to party divisions is not practicable. Only two parties, the Socialist and the Catholic *partito popolare*, founded shortly after the end of the war, are organized to any considerable extent and each has its party organs, the former having the *Avanti* of Rome and Milan for a daily and *La Critica Sociale* (Milan) as a fortnightly review; the latter, the papers of the so-called Catholic Trust, chief of which are the *Corriere d'Italia* (Rome), *Italia* (Milan), *L'Avvenire* (Bologna), and *Il Momento* (Turin).

The remaining Italian newspapers can in general only be distinguished individually or according to the politician they support. Thus, in Rome, *La Tribuna*, which was Giolittian, was opposed by *Il Giornale d'Italia*, which upheld the policy of Baron Sonnino; and in Turin the Giolittian *Stampa* had as a rival the *Gazzetta del Popolo*. The most important Radical paper is *Il Secolo* (Milan), whose Roman counterpart is *Il Messaggero*.

In addition to the newspapers already mentioned, the following deserve notice: In Milan, *La Perseveranza*, *La Sera* and *Il Sole*, the last of which specializes in economics and finance; in Venice, *La Gazzetta de la Venezia;* in Genoa, *Il Secolo XIX*.

There are a considerable number of excellent Italian reviews, of which the most important are the fortnightly *Nuova Antologia*, the Catholic literary review *Vita e Pensiero*, *La Critica* of Naples, the philosophical, historical and literary review edited by the philosopher Benedetto Croce, the political review *L'Unità*, the political and literary *Rassegna Italiana*, the cultural paper *Il Marzocco* of Florence, and the two purely literary reviews, representative of the younger Italian writers, *La Voce* and *La Ronda*.

A complete list of Italian papers, together with other information concerning the Italian press, is given every year in the *Annuario della Stampa*, published at Rome.

(6) SWITZERLAND.—During the World War Switzerland became an important centre from the point of view of the press. The geographical position of the Confederation made it the propagandist cockpit of Europe, and not only the leading nations but all the small peoples with a cause to advocate, such as Georgians, Lithuanians, Ukrainians, took care to see that their arguments were presented in the Swiss press or in newspapers specially established for the purpose. After the war had been proceeding for some time the Federal Council found it necessary to curtail the supplies of paper and prohibit the foundation of new papers, while their Government regulations sought to prevent the Swiss press from controverting the official policy of strict neutrality with regard to the various Governments engaged in the war. This did not prevent open expression of sympathy with one side or the other on the part of practically all Swiss newspapers. The French-Swiss were on the whole pro-French and pro-Entente generally, although certain of the more important—such as the *Journal de Genève*, whose wide continental circulation and reputation were even more increased—did not forget to be Swiss first. In German-speaking Switzerland German propaganda was from the beginning extremely active in the press, but the most responsible papers, in spite of a certain admiration for German institutions and culture, remained, generally speaking, open-minded. The *Neue Zürcher Zeitung* in particular deliberately adopted the policy of opening its columns to both sides, and was in consequence widely read outside Switzerland, particularly in Germany and Austria, a statement which may be applied also to the *Basler Nachrichten*, *National Zeitung* (Basel) and the *Bund* (Bern).

In addition to those named the following were the most important Swiss papers at the end of 1920: *Tribune de Genève*, *Gazette de Lausanne; Züricher Post*, *St. Galler Tagblatt*, *Vaterland* (Lucerne), the leading German-Swiss Catholic papers; *Berner Tagwacht*, *Zürcher Volksrecht* and *Basler Vorwärts* (three of the most important Social Democratic daily papers); *Gazzetta Ticinese* (Lugano), *Il Dovere* (Bellinzona).

The chief reviews were, in French-speaking Switzerland: *Bibliothèque Universelle* (Lausanne), *Semaine Littéraire* (Geneva), *Revue Romande* (Lausanne), and the *Revue de Genève*, founded in 1920. During the war, too, the *Revue Politique Internationale*, which numbered among its contributors distinguished writers from all countries and was founded in Paris a few months before the war, was transferred to Lausanne, where it continued to appear until the Armistice in 1918. Among German-Swiss reviews may be named the fortnightly *Wissen und Leben* (Zürich) and the monthly review of literature and art, *Schweizerland* (Coire).

*L'Annuaire de l'Association de la Presse Suisse* (*Jahrbuch des Vereins der Schweizerischen Presse*) is the standard work of reference on the subject. (L. M.)

### (7) UNITED STATES

In 1920 there were fewer newspapers in the United States than in 1900, but their circulation was very nearly twice as great. It was estimated in 1920 that there was then published every day one copy of a daily newspaper for every fourth inhabitant, including children, illiterates, and the mentally incompetent. The first decade of the century had been one of constant growth in the number of newspapers as well as in circulation; it was also the period which saw the culmination of the conditions introduced into American journalism by the sensational or "yellow" press.

In 1921 it could hardly be said that confidence in the press had largely increased among American readers, or that it had regained that older editorial influence, the loss of which was so generally admitted. The older generation, to whom the New York *Tribune* meant Horace Greeley, the New York *Sun* Charles A. Dana, or the Chicago *Tribune* Joseph Medill, had seen the golden age of American journalism. With the growth of the newspaper audience, both the character and influence of the newspaper had altered. The dominant factor in successful newspaper editorship had become either the exploitation of news or the promotion of profits, principally through advertising. Where the newspapers had become corporate properties with what might be called "absentee" owners, these conditions were aggravated. Nevertheless a reaction for the better was already noticeable during 1910–20. One of the influences which helped it was the very agency to which much of the demoralization of the press was commonly attributed, namely advertising.

In 1914, according to the Government census figures, the total amount derived by American newspapers from subscriptions and sales was $99,541,860, while the advertising revenues were nearly double this amount, the exact figure being $184,047,106. One of the clearest evidences of the actual influence of advertising was in the changing attitude towards circulation. Mr. Whitelaw Reid, for many years editor-in-chief of the New York *Tribune*, wrote in 1900 that a great circulation, no matter among what classes, was then regarded as the only evidence of success and the only way to make a newspaper sold below cost ultimately a source of profit. That was perhaps a natural theory to adopt in the days when the potency of advertising on a large scale was first being tested and exploited. Its fallacy was discerned even then by far-sighted publishers and advertisers. That the interests of advertising did not lie exclusively in a large circulation was perceived as early as 1891 by Mr. Adolph Ochs, who not only profited greatly by his discovery, but in his administration of the New York *Times* set an example which was of salutary effect throughout the country. In a speech delivered before the National Editorial Association, Mr. Ochs, then the proprietor of a newspaper in Chattanooga (Tenn.), said: "It is not alone the

circulation that the newspaper has that fixes its value as an advertising medium. It is more the character and standing of its readers, the appearance of the paper, its news features, its editorial ability and its general standing in the community." That was in 1891, the very moment when the "yellow" press was making its first success. Five years later Mr. Ochs acquired the New York *Times*, and set about to rebuild it, a task of formidable proportions, for the *Times*, in spite of an honourable history, was then struggling along with a circulation of hardly more than 10,000. Within 20 years the *Times* had built up a circulation of 325,000 (1916) and its total annual revenue was in the neighbourhood of $5,000,000, two-thirds from advertising.

The encouraging example of the New York *Times* and a few other newspapers, notably the Chicago *Daily News* and the Kansas City *Star*, was coincident with an advance in the theory and practice of advertising which had widespread results. It came to be seen that the effect of an advertisement was influenced to a large degree by the character of the newspaper in which it appeared, and that an incredulous reader of the news columns was likely to be an incredulous reader of the advertisements. Experience also showed that the character of the circulation was quite as vital as its extent.

Thus the influence of advertising, coupled with a natural desire for prestige and authority, served to act as a corrective for some of the worst evils that had been noted in the American press. Towards the end of the decade there was a marked improvement in the accuracy and impartiality of the news columns.

During the World War, most valuable work, particularly in aiding the Government, was done by the American press. In promoting the draft and Liberty Loans, the newspapers gave notable assistance. Mr. J. M. Lee (*American Journalism*, 1917) notes that the outbreak of the war temporarily at least revived an interest in the editorial; he adds that "once again American journalism found itself divided into two groups, one which was pro-Ally, the other which was pro-German." As a matter of fact, the English-language pro-German press was relatively insignificant and lacking in influence, even at the beginning of the war, and to speak of the other press, the truly American press, as pro-Ally in the same sense that the pro-German newspapers were pro-German is false. The pro-German press put German interests above all other interests, American as well as Allied, while it could not be said that the American newspapers, even though largely committed to the Entente cause, ever proposed a sacrifice of American rights and principles. The distinction is important, because it explains why much German propaganda failed. German interests, for example, advanced funds for the purchase of an English-language newspaper in New York, but as soon as the heavy hand of German propaganda was seen in its news and editorial columns it fell into disrepute.

The German-language press, which during the period of neutrality had sorely tried American patience, became after the United States entered the war a positive menace. "The bulk of the German-American press in this country," said the *Atlantic Monthly* in July 1917, "consists frankly of enemy papers," and there was a very natural demand for their suppression. Congress, however, preferred to rely on regulation, and various powers to this end were concentrated in the hands of the Postmaster-General by the laws of June 15 1917 (the Espionage Act) and Oct. 6 (the Trading with the Enemy Act). Under these laws seditious matter was made non-mailable, besides subjecting the publisher to heavy penalties, and the Postmaster-General was given extraordinary powers to determine what was mailable and under what circumstances. Foreign-language periodicals, for example, were required to file with the Postmaster-General translations of all articles commenting on the war unless by special licence they were absolved from this obligation. Another agency was also created to deal with questions of war news and opinion. This was the Committee on Public Information, appointed by the President shortly after the United States entered the war, which sought at the outset to impose a "voluntary censorship" on the press. Its activities, however, were chiefly devoted to spreading propaganda for the American cause.

Most of the German-language press avoided suppression or prosecution by adroitly disguising its known sentiments. The Espionage Act was, as a result, invoked mainly in cases such as that of the Milwaukee (Wis.) *Leader*, an English-language newspaper edited by Victor Berger. The Postmaster-General revoked the permit under which the paper was mailed as second-class matter on the ground that it had frequently violated the Espionage Act. In March 1921 the U.S. Supreme Court upheld the action of the Postmaster-General, and asserted the doctrine that this official was empowered at any time to deny future mailing rights to any periodical which had in the past contained articles that seemed to him unmailable. There was no question as to the anti-Government tendency of the *Leader*, but advocates of free speech saw in this and similar decisions a possible menace to the liberty of the press, especially if the same powers were to be exercised by the Postmaster-General in times of peace. The subject was exhaustively treated by Professor Chafee, of the Harvard Law School, in his *Freedom of the Press*, 1920 (see also Professor Chafee's article in 112 N.Y. *Nation* 428).

According to the census of 1914, the number of foreign language publications in the United States was about 1,450, of which the dailies had a combined circulation of 2,600,000 per issue, and the weeklies a circulation of 4,240,000, as against 1,786,000 for the dailies and 2,544,000 for the weeklies in 1909. There were in 1914 160 daily newspapers printed in more than 20 languages and dialects. Of these the German newspapers were most numerous. At the outbreak of the World War there were 55 German-language dailies with a circulation per issue of 823,000. Toward the close of the decade there was a marked decrease in the number of foreign-language papers, especially those printed in German. The total number of German papers declined from 490 in 1918 to 278 in 1920, but this decline was due in part to conditions which affected the entire newspaper industry.

The following table shows the extent of the foreign language press in 1920:—

*The Foreign-Language Press.—(United States.)*

| Language | Total No. | No. of Dailies | Dailies, Total circulation per issue (Estimated) | No. of Weeklies | Weeklies, Total circulation per issue (Estimated) |
|---|---|---|---|---|---|

* Includes Albanian (3), Bulgarian (1), Esthonian (1), Belgian-Flemish (2), Lettish (2), Hebrew (4), Ladino (Spanish Jew) (2), Persian (1), Rumanian (3), Welsh (2).

The war years brought about a serious crisis in the supply of newsprint. This commodity, which in 1873 cost 12 to 13 cents a pound and in 1880 6·92 cents, could be purchased in 1897 for 1·5 cents. Even in 1915 it could be bought for 1·91, but after that it went to higher prices than had obtained for 20 years, as the following table shows:—

*Prices of Newsprint (cents per pound).*

| | | | |
|---|---|---|---|
| 1913 | 2·01 | 1917 | 3·17 |
| 1914 | 1·95 | 1918 | 3·72 |
| 1915 | 1·91 | 1919 | 3·65 |
| 1916 | 2·03 | 1920 | 6·50 |

The newsprint manufacturers justified these prices on the score of increased cost of production, but to a large extent they were undoubtedly famine prices due to the inadequacy of the supply to meet an unparalleled demand. There were charges also of a conspiracy on the part of the producers to maintain high prices, and the Federal Trade Commission endeavoured at various times to ameliorate these conditions. A canvass made by a trade organ early in 1920 showed that only 25% of American newspaper publishers were then assured of an adequate supply of newsprint for the ensuing year. Of the remainder 20% could look forward to ½ to ⅔ of their requirements, while 55% had no assurance of being able to get the newsprint they needed. Yet the production of newsprint in the United States and Canada was constantly increasing as the following figures indicate:—

*Production of Newsprint.*
*(Tons)*

| | | | |
|---|---|---|---|
| 1904 | 913,000 | 1915 | 1,728,000 |
| 1909 | 1,326,000 | 1916 | 2,000,000 |
| 1914 | 1,698,000 | 1919 | 2,183,000 |
| | 1920 | 2,395,000 | |

Clearly the scarcity was created by the great increase in circulation following the outbreak of the war and by the enormous demand for advertising space. Not only had circulation doubled, but the number of pages in the average newspapers had been largely increased. In order to protect themselves certain newspapers began to acquire properties for the production of newsprint, but this was only possible for the strongest journals.

Shortage of newsprint was not the only difficulty encountered. To give a basis of comparison it is of interest to note some of the figures on cost of production for the New York *Times* for the year 1916. In that year, according to the publisher, the *Times* was employing 1,200 persons and had a pay-roll of $32,000 a week, which was about equally divided among the mechanical, the news and editorial, and the business and executive departments. With a circulation of 325,000 the paper consumed 100 tons of newsprint a day. Telegraph and cable expenses averaged about $100,000 annually, not including the cost of messages received through news agencies, nor of salaries and expenses of foreign correspondents. Cost of newspaper delivery exceeded $5,000 a week. In May (31 days) the combined issues of the *Times* aggregated 926 pages, of which 47·67% was advertising. As already noted the revenue from sales was about $1,500,000 annually, or approximately one-half the revenue from advertising. The total receipts from a single issue of the Sunday *Times* frequently amounted to $50,000. At this period the rise in production costs was just beginning to be felt by the newspaper industry. In 1921 it seemed possible that the figures of 1916 might again be typical if wages and prices, especially of newsprint, continued to decline. But in the period beginning somewhat before 1916 and ending with the close of the decade, there was the sharpest advance in prices ever known in the newspaper industry. These advances were summarized by the president of the American Newspaper Publishers' Association as follows: Newsprint, 232%; cost due to increased circulation, 28%; news and "features," 300%; ink, 75%; machinery, 50 to 100%; delivery service, 400%; printers' wages, 108%; pressmen, 102%; stereotypers, 94%; office help, 84%; drayage, 75%; freight, 107%; printing-press blankets, 150%; telephone, 15%; electric power, 90%; fuel, 40%. Costs as a whole were said to have risen 200%. To offset these increased costs both the selling price of the newspapers and advertising rates were advanced. After 1916 nearly all newspapers that had been one cent were advanced to two cents, and in 1919 and 1920 a great number of dailies, chiefly evening newspapers, went to three cents, a price which had not been general for more than 20 years.

Curiously enough these increases seemed to have had only a temporary effect in restricting circulation. It was thought that the close of the World War would cause a marked decline, but the increasing popularity of the newspaper seemed to have had less temporary foundations. New readers had been taught the newspaper habit, and many people began to buy more than one paper. These habits persisted even after the immediate occasion had disappeared.

This extraordinary circulation was rather a burden than otherwise until advertising rates could be adjusted to cover the expense. Ultimately, however, advertising rates were advanced nearly, if not quite, 100%, and in the meantime some newspapers, partly to save newsprint, arbitrarily restricted the size of their circulation. The stronger newspapers undoubtedly profited greatly during this period. On the other hand, the high production costs, coupled with the scarcity of newsprint, were the chief reasons for the decline in the number of newspapers and periodicals which began in the years 1916 and 1917. This decrease, together with circulation figures for the period, is shown in the following tables:—

*Number of newspapers and periodicals in the United States.*
*(Based on Ayer's newspaper directories.)*

| | Daily | Weekly | Semi-Weekly | Monthly | Semi-Monthly | Miscellaneous* | Total |
|---|---|---|---|---|---|---|---|
| 1810 | 27 | 282 | 37 | .. | .. | 15 | 361 |
| 1850 | 254 | 1,902 | 31 | 100 | 95 | 144 | 2,526 |
| 1900 | 2,200 | 15,681 | 515 | 2,328 | 261 | 256 | 21,235 |
| 1910 | 2,470 | 16,269 | 620 | 2,767 | 264 | 197 | 22,587 |
| 1913 | 2,483 | 16,266 | 601 | 2,879 | 361 | 387 | 22,977 |
| 1914 | 2,502 | 16,323 | 616 | 2,981 | 348 | 397 | 23,167 |
| 1915 | 2,494 | 16,091 | 605 | 3,064 | 341 | 445 | 23,040 |
| 1916 | 2,514 | 16,165 | 590 | 3,250 | 353 | 515 | 23,387 |
| 1917 | 2,465 | 15,635 | 532 | 3,261 | 358 | 591 | 22,842 |
| 1918 | 2,428 | 14,771 | 483 | 3,073 | 345 | 564 | 21,664 |
| 1919 | 2,398 | 14,008 | 487 | 3,156 | 360 | 603 | 21,012 |
| 1920 | 2,374 | 13,894 | 476 | 3,183 | 390 | 624 | 20,941 |

*Includes tri-weekly, bi-monthly, quarterly and other periodicals not included elsewhere in this table.

The number of towns and cities in which these publications were issued was as follows in the years indicated: 1914—10,985; 1916—11,035; 1918—10,461; 1920—10,160.

*Circulation of daily newspapers in the United States.*

| | | No. of dailies | Circulation per issue |
|---|---|---|---|
| 1850 | | 254 | 758,454 |
| 1900 | | 2,235 | 15,102,156 |
| 1909 | | 2,467 | 24,211,977 |
| 1914 | Morning | 794 | 11,692,368 |
| | Evening | 1,786 | 17,085,086 |
| | Total | 2,580 | 28,777,454 |
| 1920 | Morning | 625 | 11,700,000† |
| | Evening | 1,749 | 18,300,000† |
| | Total | 2,374 | 30,000,000† |
| 1920—Sunday | | 600† | 15,000,000† |

† Estimated. The figure for the total number of daily newspapers in 1914 is that of the Government census and differs slightly from that given in the previous table. The circulation of weekly newspapers in the United States was in 1920 about 20,000,000.

The decline in weekly newspapers, for the most part published in country towns, was greatest, but many daily newspapers were also forced to suspend or to effect mergers with rival journals. In some instances the opportunity was grasped by men who had made a success in other fields to acquire newspaper properties. Thus, Frank A. Munsey, proprietor of *Munsey's Magazine* and other periodicals, purchased in New York the *Sun* (1916), the *Herald* and the *Evening Telegram* (1920). Eventually Mr. Munsey discontinued the *Sun* as a morning paper, that title being given to what was hitherto known as the *Evening Sun*, which he had also acquired. In 1919 the pub-

lishers of the Chicago *Tribune* started a daily illustrated paper in New York, the *News*, which in 1920 attained a circulation of more than 300,000. In Chicago the movement toward consolidation had begun earlier. The Chicago *Inter-Ocean*, which lost public support through its espousal of the Lorimer cause (*see* ILLINOIS), was purchased (1913) by the Chicago *Record-Herald*, and the two papers were consolidated under the name of the Chicago *Herald*. Later the *Herald* encountered financial difficulties and was purchased by William Randolph Hearst, who merged it with his morning newspaper under the name *Herald and Examiner*. For a time this left Chicago with only two morning newspapers, Mr. Hearst's organ and the *Tribune*. In 1920 a morning business daily, the *Journal of Commerce*, was started.

The changes occurring during the latter part of the decade might have been expected to foster a tendency toward grouping large numbers of newspapers under one ownership. Broadly speaking, no such development took place, and there was in 1921 no newspaper owner in America except William Randolph Hearst whose journalistic ventures were comparable in extent with those of (for example) Lord Northcliffe in England. Mr. Hearst established his group of newspapers largely between 1895 and 1910, and did not materially add to the number in succeeding years, although in 1913 he purchased the Atlanta *Georgian* and in 1917 the Boston *Advertiser*. Within the decade 1910–20 Mr. Hearst also entered the field of periodical journalism; by 1920 he had become proprietor of the *Cosmopolitan Magazine*, *Hearst's Magazine*, *Good Housekeeping*, *Harper's Bazar*, *Motor Magazine* and *Motor Boating*, as well as the 13 newspapers which constituted the Hearst group. The Scripps-McRae League, comprising about 22 newspapers in the middle west, was not increased between 1911 and 1920.

On the other hand, there was a marked tendency to form associations of newspapers for sharing the expense of gathering news and procuring pictures, "features," and similar material. The possibilities in this direction were illustrated somewhat earlier by the development of an enterprise known as the newspaper syndicate, which first acquires the material, usually fiction, special articles and comic pictures, and then sells publication rights to newspapers all over the country. S. S. McClure, who subsequently established *McClure's Magazine*, is said to have started the first newspaper syndicate about 1885. Besides these private enterprises many were undertaken by individual newspapers, while still others were controlled coöperatively.

Mechanical improvements in the production of American newspapers were largely in the direction of greater refinements of those inventions, such as the linotype composing machine and the rotary press, which had made the modern newspaper possible. One process, the rotogravure, introduced from Germany in 1912, afforded the means whereby the larger newspapers could produce supplements containing pictorial reproductions of excellent quality. It is a photomechanical process by which the illustrations are etched on a copper cylinder; impressions resembling photogravure can then be run off at the rate of 3,000 or more an hour. There were approximately 50 newspapers in 1920 which published rotogravure supplements, usually as part of their Sunday editions. With the multiplication of supplements of various kinds it became customary to print and distribute to dealers practically all of the Sunday edition except the distinctively news sections before the date of publication. After receiving the news sections the dealers would assemble them with the supplements which had been distributed in advance. In obtaining news great use was made of the wireless, especially as a substitute for the cable in transmitting messages from Europe.

The mechanical difficulty of making a rapid distribution over very large areas has been the chief factor in America in preventing the development of newspapers having a wide national circulation. It takes at least 20 hours for a New York newspaper to reach Chicago by railway, and to reach the Pacific coast requires several days. There have been, in addition, certain transportation difficulties imposed by the railways themselves; special newspaper trains are much less common than in England. The result has been the development of a strong newspaper press in practically all large cities, and this press naturally places more emphasis on local or sectional news than it would if its circulation were less restricted in area. A few journals are, of course, read beyond the local limits of quick distribution; some of them, indeed, enjoy a prestige that is nation-wide. Yet even the New York *Times* had in 1921 a circulation throughout the country at large of only 73,600 (less than one-quarter of its total circulation). The percentage of outside circulation in the case of the Chicago *Tribune* was somewhat higher, but it was largely confined to the states immediately surrounding Chicago. If, however, papers of this character could be placed on sale in smaller cities everywhere at approximately the same time as the local newspapers, it is clear that they could enormously increase their circulation in all parts of the country. A national rather than a sectional circulation would ultimately have the effect of broadening the newspaper's scope and strengthening its editorial independence. The establishment of the Government airplane mail service after the close of the World War gave promise that this method of distribution might enable certain newspapers to achieve a truly national circulation. Such a development might conceivably be regarded at some future time as the greatest single advance in American journalism.

*Periodicals.*—The magazines and periodicals in the United States do not suffer from the handicap which has limited the circulation of even the great newspapers. A magazine can be printed several days and even longer before the date of publication; it can therefore be placed on sale all over the country at the same time. As a consequence American periodicals have taken the whole nation for their field, and a single magazine will have nearly as large a circulation in the west as in the east. In this development the magazines were favoured greatly by an extremely low second-class mailing rate, which up to 1917 was a cent a lb. though the expense in carrying this matter was rarely less than eight cents a lb., at which rate books were carried. The result was a loss to the Government amounting to many millions annually on magazines alone, a loss which was defended on the score of fostering education and national unity. The War Revenue Act of 1917, however, largely increased the rates applicable to periodicals, in spite of considerable protest. The new rates were graded according to the proportion of space devoted to advertising, and annual increases were provided for each year up to 1921, when a maximum was reached. This maximum involved a general rate of one and a half cents a lb. for reading matter, and special rates for that part of the magazine devoted to advertisements ranging from two cents for the first and second zones to 10 cents for the eighth zone, these zones being fixed according to the distance from the post-office at which the magazine was mailed. Even these rates had not, in 1920 at least, materially affected the prosperity of the magazines, though efforts were still made to change them. In the meantime the conditions favourable to the establishment of national magazines likewise tended to discourage local efforts, with the result that at the close of the decade 1910–20 nearly all the more important magazines were published in New York. The most notable exceptions were the *Atlantic Monthly*, published in Boston, and the Curtis publications, *Ladies' Home Journal*, *Saturday Evening Post* and *Country Gentleman*, in Philadelphia.

The development of the popular magazine in the United States was almost coincident with the development of the sensational newspaper. In both instances cheap paper, machine production and an ever-increasing number of readers were determining factors. The cheaper magazines benefited particularly by the invention of the process of photo-engraving which came into general use between 1890 and 1895; illustrations that had previously cost $100 and required a month's time could now be had for $10 and in one day. That period saw the beginning of a large number of magazine ventures, many of which, after various turns of fortune, still survived in 1920.

Had it not been for the national audience which the magazine could command it is quite probable that the popular monthly of the type of *Everybody's* (established 1899), *McClure's* (1893), and *Munsey's* (first issued as a monthly in 1891), would have seriously endangered the existence of the older and more distinctive literary magazines such as the *Atlantic*, *Harper's*, *Scribner's* and the *Century*. Yet of these periodicals the *Atlantic* was the only one to show a marked growth in circulation between 1900 and 1920. *Harper's*, for example, had less circulation in 1920 than in the latter part of the 19th century, although the quality and attractiveness of its contents showed no diminution. But magazines as a whole suffered no such neglect, for in the United States no home in which there is any pretext of intellectual interest is without magazines.

During 1910–20 a five-cent illustrated weekly, the *Saturday Evening Post*, began to surpass all others both in circulation and advertising returns. (In 1920 the *Post* had more than 2,000,000 circulation.) It was therefore widely imitated in the hope of duplicating its success. That success was apparently founded chiefly on a special variety of popular fiction, of which it publishes large quantities. In no previous period was so much space given to fiction by American magazines, and in no previous period were American magazines so thoroughly given over to mere entertainment. The editors seemed to have concluded with one accord that the public

was tired of argument and instruction. As if to fill this void, there were started during the decade a number of weekly journals of opinion, of which the *New Republic* (1914), the *Weekly Review* (1919) and the *Freeman* (1920) may be mentioned. The *Nation* (founded in 1865), which had long occupied a unique position as a politico-literary weekly, entered into a new and distinctly radical phase during the decade; it was avowedly to combat these radical tendencies that the *Weekly Review* was undertaken by a group of men, some of whom had served on the staff of the old *Nation*.

Two serious reviews, comparable in character to the reviews of Great Britain, were started after 1910, the *Yale Review* in the following year and the *Unpopular Review*, later named the *Unpartizan Review*, in 1914. Both are quarterlies. Another new magazine of value to the student of affairs was the *Current History Magazine*, established in 1914 by the New York *Times*. The *North American Review*, among whose editors were some of the most famous names in American literature, celebrated its first centennial in 1915. Professor Brander Matthews expressed the opinion, 1918, that the literary level was higher than 50 years before.

A distinctive feature of the later development of American periodical journalism was the extraordinary success achieved by women's magazines. These enjoyed a steady growth without experiencing those vicissitudes of fortune which marked the history of other ventures. The *Ladies Home Journal* was a successful pioneer in this field. Characteristic also of the period was the growth of technical and trade organs, and the decline of the religious press.

Bings, *The Country Weekly* (1917); Algernon Tassin, *The Magazine in America* (1916); James Bryce, *Modern Democracies* (1921) and Chapters on American Opinion. (H. B.*)

**NEWTON, ERNEST** (1856–1922), English architect, was born Sept. 12 1856. After having been at school at Uppingham, he entered the office of Norman Shaw, with whom he spent the following six years. Here in the company of a gifted band of young students the influence of this talented teacher made—as was evidenced more especially in Newton's earlier days—a strong impress on his trend of design, and helped to imbue him with that appreciative feeling for, and grasp of, English Renaissance domestic architecture which characterize his work. Established on his own account there fell to him much work of this special nature, for his province consisted almost entirely in the designing of new country houses or modifying or adding to existing ones. His few excursions into architecture of an ecclesiastical nature include the house of retreat and chapel for the Sisters of Bethany, and St. Swithin's church, Hither Green, the latter an interesting and successful departure from the normal plan, with a choir diminishing in width towards the east end. Newton's domestic work shows in its later phases more than in his first essays the influence of the architecture of the 18th century. Still, neither then nor earlier is it rigidly bound by tradition, but speaks an educated individuality. Amongst his houses are Buller's Wood, Chiselhurst; Redcourt, Haslemere; Steephill, Jersey, a house set in an old and typical Jersey garden; and Ardenrun Place, Blindley Heath. His literary work includes *A Book of Houses* and—his particular *spécialité*—*A Book of Country Houses*.

In the first year of the World War, Newton's position as president of the Royal Institute of British Architects and his professional acquirements were utilized by the Government, and under the Ministry of Munitions and its Labour Department he was largely responsible in 1916, and entirely so in 1917, for dealing with the control of every type of constructional work, including such important undertakings as railways and electric schemes. He also, as expert adviser, considered claims for exemptions in the building trades generally—a post of great responsibility. He became R.A. in 1919, and was awarded a C.B.E. in 1920. He died in London Jan. 25 1922.

**NEW YORK (STATE)** (*see* 19.594).—The pop. of the state was 10,385,227 in 1920 as compared with 9,113,614 in 1910, a gain of 14% or 0·9% less than that for the United States. The average pop. per sq. m. in 1920 was 217·9 as compared with 191·2 in 1910 and 152·5 in 1900. In 1920 the urban pop. (in cities with 2,500 or more inhabitants) was 8,589,844 or 82·7% and the rural pop. 1,795,383 or 17·3 per cent.

The cities having a pop. of over 20,000 in 1920, and their percentage of increase 1910–20, are as follows:—

| | 1920 | 1910 | Increase per cent |
|---|---|---|---|
| Albany | 113,344 | 100,253 | 13·1 |
| Amsterdam | 33,524 | 31,267 | 7·2 |

| Utica | 94,156 | 74,419 | 26·5 |
| Watertown | 31,285 | 26,730 | 17·0 |
| White Plains | 21,031 | 15,949 | 23·1 |
| Yonkers | 100,176 | 79,803 | 25·6 |

*Decrease.

According to the census report of 1916 there were 4,315,404 church members in the state, distributed as follows: Roman Catholic, 2,745,552, or 63·6%; Methodist Episcopal, 328,250, or 7·6%; Protestant Episcopal, 227,685, or 5·3%; Presbyterian, 222,888, or 5·2%; Baptist, 182,443, or 4·2%; Jewish, 113,924, or 2·6%; Lutheran, 73,581, or 1·7%; Reformed, 66,773, or 1·5%; Congregational, 65,021, or 1·5%; others, 289,287, or 6.7 per cent.

*Agriculture and Stock-raising.*—In 1919 New York ranked thirteenth among the states in the crops produced, the total value of farm products being $498,179,000. The state ranked first in the production of hay and potatoes. In 1910 the total number of farms in the state was 215,597 and the acreage 22,030,367, of which 67·4% was improved. In 1920 the number of farms had decreased to 193,060. In 1919 the state produced 6,579,000 tons of hay; 35,260,000 bus. of corn; 11,178,000 bus. of wheat; 29,580,000 bus. of oats; 2,486,000 bus. of barley; 1,932,000 bus. of rye; 5,126,000 bus. of buckwheat; 39,567,000 bus. of potatoes; 16,800,000 bus. of apples; 1,530,000 bus. of pears; 1,648,000 bus. of peaches; and 3,483,000 lb. of tobacco. The number of sheep in the state has been steadily decreasing. In 1910 there were 953,908; in 1920, 824,000. The state produced 4,022,000 lb. of wool in 1919. The dairy business is one of the most important. In 1920 there were in the state 1,493,000 dairy cows, a larger number than in any other state except Wisconsin. Other cattle numbered 909,000. There were 560,000 horses and 920,000 swine.

*Minerals.*—In 1916 New York ranked twentieth among the states in the value of minerals produced. The mineral products were valued at $45,783,230, as against $34,317,594 in 1911. The clay products were valued (1916) at $11,755,012; cement, $5,752,809; iron ore, $5,571,429; stone, $5,342,954; natural gas, $2,524,115; petroleum, $2,190,195; salt, $3,698,798; sand and gravel, $2,644,829. In 1918 the values were $6,568,746, cement; $5,673,131, natural gas; $5,802,870, iron ore; $3,307,814, petroleum.

*Manufactures.*—New York ranks first among the states in the value of manufactured products, and during the five years following 1909 the output increased rapidly. The 1914 census reported 48,203 establishments (1909, 44,935) with 1,057,857 wage-earners (1909, 1,003,981), receiving $631,042,000 and with a capital of $3,334,278,000. The cost of materials was $2,108,607,000 (1909, $1,856,904,000); the value of the product, $3,814,661,000 (1909, $3,369,490,000); and the value added by manufacture, $1,706,054,000 (1909, $1,512,586,000). The industries whose products were valued at more than $100,000,000 were:—

| | Wage-earners | | Value | |
|---|---|---|---|---|
| | 1914 | 1909 | 1914 | 1909 |
| Clothing | 189,763 | 189,467 | $583,942,000 | $538,593,000 |
| Printing and publishing | 64,020 | 63,120 | 257,268,000 | 216,946,000 |
| Foundry and machine shops | 66,690 | 64,066 | 173,429,000 | 154,370,000 |
| Slaughtering, meat-packing | 6,641 | 6,110 | 148,105,000 | 127,130,000 |
| Sugar refining | 4,899 | | 124,941,000 | |
| Bread and bakery products | 27,002 | | 109,227,000 | |

There were in 1914 17 industries with products exceeding $50,000,000 in value, 21 with products between $25,000,000 and $50,000,000 in value, and 25 with products between $10,000,000 and $25,000,000—a total of 63 industries each with products valued at more than $10,000,000. The report showed 161 industries, each of which had a product valued at more than $1,000,000. In 1914, 87%, in 1909, 86·8% of the value of the manufactured products of the state was reported from cities and villages with 10,000 or more inhabitants. Of the 48,203 industrial establishments in the state in 1914, 29,621, or 61·5%, were located in New York City. More than one-half of the wage-earners and more than three-fifths of the value of the state's manufactured products were in both 1909 and in 1914 reported from New York City. Other important manufacturing centres were: Buffalo, with products in 1914 valued at $247,516,000; Rochester, $140,696,000; Yonkers, $67,222,000; Syracuse, $52,163,000; Schenectady, $48,762,000; Niagara Falls, $44,816,000; Troy, $39,929,000; Utica, $30,490,000; and Albany, $25,211,000.

*Transportation and Commerce.*—In 1915 the operated railway mileage was 8,824, the most important lines being the New York Central; the Delaware and Hudson; the Lehigh Valley; the West Shore; the Erie; the New York, Ontario and Western; the Pennsylvania; the Delaware, Lackawanna and Western; the Rutland; and the Long Island. In 1917 there were in the state 4,893 m. of electric railway which gave employment to 61,434 persons. These lines carried 2,492,325,233 revenue passengers. In 1920 there were 13,453 m. of improved roads in the state. During the previous year $17,761,545 was spent for highway construction and $6,219,190 for highway maintenance.

New York spent large sums for canal improvements. The improved Erie Barge Canal was opened from Troy to Buffalo in May 1918. The Champlain and the Oswego Barge Canals have also been completed. Up to April 1 1920 the total expenditure for canal improvements, under bond issues, since 1902 amounted to approximately $150,252,499. The canal mileage of the state in 1920 was: Erie Canal, 361; Champlain Canal, 81; Black River Canal, 89; Oneida Lake and Canal Feeder, 7; Oswego Canal, 77; Cayuga-Seneca Canal, 23; total, 638. The commerce on the canals suffered a rapid decline during the decade 1910–20. In 1910, 3,073,412 tons of products valued at $59,042,178 were carried; in 1915, 1,858,114 tons valued at $30,610,670; in 1917, 1,297,225 tons valued at $24,757,077; and in 1919, 1,238,844 tons valued at $43,972,603. New York ranks first among the states in commerce. In 1920, 5,014 vessels, with a total tonnage of 15,049,744, entered the port of New York and 4,588 vessels, with a total tonnage of 14,275,455, cleared. In that year the value of merchandise imported was $2,904,844,143. The value of domestic exports was $3,293,304,084.

*Education.*—The university of the state of New York, a supervising and examining institution, not one for teaching, is the State Department of Education. It is governed by 12 regents, one elected each year for a 12-year term by a joint ballot of the two Houses of Legislature. The board of regents elects the president of the university and the commissioner of education, both offices being held by the same person. According to the 1910 census there were in the state 2,454,428 persons between the ages of 6 and 20. Of these, 1,563,374 or 63·7% were attending school. In addition to these there were in school 55,773 children under 6 years of age, and 31,716 persons 21 years old and over, a total of 1,650,863.

The Thirteenth Annual Report of the Education Department, for the school year ending July 31 1916 contains the following summary of school attendance: common elementary schools, 1,454,514; special elementary schools, 940; common high-schools, 171,263; special high-schools, 4,152; academies, 53,461; normal schools, 8,125; teachers' training classes and schools, 4,422; universities, colleges, professional schools and other higher institutions, 56,116; private schools of all grades, exclusive of academies as enumerated above, estimated, 275,000; Indian schools, 842; evening schools, 173,878; evening vocational schools, 27,688; trades and vocational schools, 17,861; total, 2,248,262. The total number of teachers was 63,954, of whom 42,957 were employed in the common elementary schools. The net value of school property was estimated at $462,698,843.

During the school year ending June 1918 there were enrolled in the public schools 1,666,589 pupils. The daily average attendance was 1,299,535, and the average duration of school was 187 days. The total number of teachers was 59,187, of whom 52,508 were women. The total state expenditure for public schools was $81,058,361 (*see* also section *History* below).

*Charities and Prisons.*—The number of inmates in state institutions, almshouses, homes, reformatories, and schools for the blind and deaf, for the year ending June 30 1919, was: number in all institutions, July 1 1918, 62,540; number received during the year, 96,082; total supported, 158,622, of which number 142,417 were supported by public funds and 16,205 by private funds. The number discharged was 97,842. The number in state asylums and reformatories on June 30 1919 was 9,545. The State Hospital Commission, consisting of three members appointed by the governor and the Senate for 6-year terms, has the supervision of the state hospitals for the insane. On June 30 1919 there were 37,607 patients in the civil state hospitals; 1,422 in hospitals for the criminal insane; and 916 in private institutions; a total of 39,945. Of the 37,607 patients in the civil hospitals, 33,721, or 89·7%, were entirely supported by the state. The State Commission of Prisons, consisting of seven members appointed by the governor and the Senate, has supervision of all penal institutions. The pop. of the state prisons, reformatories, penitentiaries, county jails, and New York City institutions, on June 30 1919, was 11,016, and the total number of commitments to the various institutions during 1919 was 85,175. The state appropriated $36,604,579.57 for penal, charitable and curative institutions for the fiscal year ending June 30 1921.

*Finance.*—The total state debt June 30 1920 was $238,860,017, and the sinking funds amounted to $69,499,475, making the net debt $169,360,542. In addition, authorization had been granted for bonds amounting to $76,800,000, consisting of $45,000,000 soldiers' and sailors' bonus bonds, $6,800,000 barge canal bonds, $20,000,000 highway improvement bonds and $5,000,000 state forest bonds. According to Gov. Miller's message to the Legislature in Jan. 1921, the financial operations for general budget purposes for the fiscal year ending June 30 1920 were as follows:—

| | |
|---|---|
| Revenue: | |
| General property taxes | $ 15,058,317.01 |
| Special taxes | 93,018,032.15 |
| Other general revenues | 7,515,257.83 |
| Total | $115,591,606.99 |
| Expenditures: | |
| Administration, maintenance and operation | $ 47,902,427.19 |
| Fixed charges and contributions | 39,699,757.53 |
| Capital outlays | 6,422,030.75 |
| Total | $ 94,024,215.47 |
| Excess of receipts over expenditure | $ 21,567,391.52 |

Early in 1921 the comptroller made the following estimate of revenues for the year 1921–2:—

| | |
|---|---|
| General property taxes: | |
| Sinking funds, etc. | $ 13,702,340 |
| School-teachers' salaries, etc. | 19,935,000 |
| Court and stenographers' tax | 650,000 |
| Special taxes: | |
| Excise (liquor tax) | $ 200,000 |
| Corporation tax | 30,330,000 |
| Personal income tax | 16,500,000 |
| Organization of corporations | 1,500,000 |
| Transfer (inheritance tax) | 17,500,000 |
| Stock transfer (stamp tax) | 8,520,000 |
| Mortgage tax | 2,750,000 |
| Motor vehicles | 4,635,000 |
| Other revenues and receipts | 7,613,900 |
| Total estimated revenue | $123,836,240 |
| Estimated surplus, July 1 1921 | 18,745,595 |
| Total estimated resources | $142,581,835 |

When the Legislature assembled in Jan. 1921 there were submitted requests for appropriations amounting to the sum of $201,644,292.43. However, under the leadership of the governor, who demanded rigid economy, these estimates were materially reduced. The rapid increase in the cost of the state government during 1912–21 is shown by the following table of budget appropriations:—

| | Appropriations | Per Capita |
|---|---|---|
| 1912 | $43,074,192.58 | $4.61 |
| 1913 | 52,366,582.35 | 5.53 |
| 1914 | 59,465,690.97 | 6.21 |
| 1915 | 47,899,527.74 | 4.94 |
| 1916 | 63,997,271.86 | 6.51 |
| 1917 | 59,103,450.08 | 5.93 |
| 1918 | 79,742,834.21 | 7.89 |
| 1919 | 81,525,271.31 | 7.95 |
| 1920 | 95,840,983.77 | 9.22 |
| 1921 | 145,219,906.60 | 13.79 |

Two of the most important laws relative to financial administration were the Sage-Maier budget law of 1916 and the income tax law of 1919.

*Government.*—Although the constitution adopted in 1894 has been frequently amended, the government of New York underwent no fundamental alterations between 1910 and 1921. The most important change was the adoption in 1917 of the woman suffrage amendment. The Constitutional Convention of 1915 adopted far-reaching changes in organization, but all its proposals were disapproved by the electorate. The number of administrative boards and commissions has been greatly increased as the activities of the state have been extended into new fields. In 1919 these agencies, according to the governor's Reconstruction Commission, numbered 187. One of the pressing reforms

advocated both by the Constitutional Convention and by the Reconstruction Commission was the reorganization of these miscellaneous administrative agencies into a smaller number of coördinated departments under the governor's control. Another movement was directed toward the establishment of an executive budget system. Neither of these reforms was adopted. One of the most important changes in local government was the adoption by the Legislature of an optional charter law for cities.

*History.*—On Oct. 6 1910 Gov. Charles E. Hughes resigned to accept a position as associate justice of the U.S. Supreme Court. He was succeeded by Horace White, the lieutenant-governor. Among the outstanding accomplishments of Gov. Hughes's term of office may be mentioned: the enactment of a progressive inheritance tax law; the creation of a Public Service Commission with large powers; the passage of a law prohibiting race-track gambling; and the strengthening of the state child labour laws. Gov. Hughes had persistently advocated the enactment of a thoroughgoing direct primary law, but because of the opposition of the leaders of his party to this reform, the convention system survived his term of office and furnished one of the most important issues of state politics throughout the following decade. In the elections of Nov. 1910 the Democrats elected not only the governor, John A. Dix, and the other state officers, but also a majority of the state Legislature. Dix received 689,700 votes; Stimson, his Republican opponent, 622,299.

The 1911 Legislature passed a direct primary law which was a compromise, retaining the party convention for the nomination of the state ticket but providing for the nomination of most other officers by direct primaries. The Wagner-Levy election law provided that only registered and enrolled voters might make independent nominations by petition; that there be uniform registration days throughout the state; that bi-partisan election boards be established in each county; that the name of a candidate might appear only once on the ballot; and that in rural districts voters who had not voted at the previous election must register personally. Obviously one of the chief purposes of this law was to make fusion tickets and independent voting as difficult as possible. The two last-mentioned provisions were declared unconstitutional by the Court of Appeals. In the autumn elections the Republicans secured a large majority in the Assembly.

The 1912 Legislature passed a number of important measures. An amendment to the primary law allowed party organizations to make the Assembly district, instead of the election district, the unit of representation. This permitted absurdly long ballots and practically prevented everything but straight voting. Another amendment restricted the payment of money to any person for securing signatures to a designating petition. The Rapid Transit Act was amended so as to allow the building of new subways in New York City. Large appropriations were made for state and county highway construction. An amendment to the labour law restricted the hours of labour for minors in factories.

In the autumn elections of 1912 the Democrats carried the state. The vote for president was: Wilson, Democrat, 655,573; Taft, Republican, 455,487; Roosevelt, Progressive, 390,093; the vote for governor was: Sulzer, Democrat, 649,559; Hedges, Republican, 444,105; Straus, Progressive, 393,183. The Democrats elected a majority in both Houses of the state Legislature. The newly-elected governor was inaugurated Jan. 1 1913. He had for many years received the support of Tammany Hall, first as a member of the Assembly and then for 18 years as congressman.

Among the important laws enacted in 1913 were: several measures designed to insure greater safety in factories; a law establishing an eight-hour day for employees on public works; a law limiting to 54 hours a week the time that women and children under 16 might work in certain industries; a law reorganizing the Labor Department and creating one of Efficiency and Economy.

Early in April 1913 the governor sent a special message to the Legislature urging the enactment of a direct primary law which would abolish the party convention. The disagreement between the governor and Tammany Hall, which had begun over the question of appointments, developed into an open conflict over this new issue. The Legislature by large majorities refused to pass the bill which the governor favoured and substituted a measure which he in his veto pronounced an insult to the electorate. The Senate refused to confirm many of the governor's appointments. After the adjournment of the Legislature on May 3, Gov. Sulzer entered on a strenuous campaign throughout the state to arouse public sentiment for his defeated primary bill. On June 16 he convened a special session of the Legislature, but his primary bill was again defeated by large majorities and the substitute bills adopted were promptly vetoed. In the meantime, a joint legislative committee, appointed before the end of the regular session to inquire into the affairs of the several state departments, began an investigation into the governor's campaign fund. Witnesses testified that he had made false returns as to the campaign contributions he had received. Evidence was presented to the effect that a part of the fund collected had been used for speculation. When the Legislature took a recess, July 23, the governor declared the special session adjourned; but the Legislature reassembled Aug. 11. Two days later the Assembly voted, 79 to 45, to impeach the governor on eight counts. Mr. Sulzer denied the authority of the Assembly to impeach him during a special session and claimed that even a legal impeachment would not prevent his continuance in office during the trial. The governor's contentions were overruled by the Court of Impeachment composed of the 51 Senators and the 9 justices of the Court of Appeals. The trial lasted until Oct. 17, when the governor was removed from office by a vote of 43 to 12, having been found guilty on three counts: that he had filed false statements relative to his campaign receipts and expenditures; committed perjury by swearing to such false statements; and suppressed evidence before the joint investigating committee, thus committing a misdemeanour. Martin H. Glynn, lieutenant-governor, succeeded.

The elections of Nov. 1913 resulted in an overwhelming defeat for Tammany. William Sulzer, nominated by the Progressives of the Sixth Assembly District in New York City, was elected by a large majority over his Democratic and Republican opponents. Many Democratic assemblymen who had previously voted for his impeachment were defeated.

A constitutional amendment authorizing the Legislature to pass laws to protect the lives, health, or safety of employees, and permitting the enactment of workmen's compensation laws was approved by a large majority. The special session of the Legislature, which had taken a recess after the trial of Gov. Sulzer, reassembled on Dec. 18. Gov. Glynn recommended the enactment of five important measures: a direct primary law abolishing the state conventions; a ballot law modelled on that of Massachusetts; the enactment of measures to carry out the Federal constitutional amendment providing for popular election of U.S. Senators; the submission to the voters of the question of calling a state constitutional convention; and the passing of a workmen's compensation law. The Legislature adopted the entire programme. The new primary law, state-wide in character, provided for a primary ballot with the candidates grouped according to the office sought; no party columns or party emblems were allowed; designations were to be made by petition and the state convention was abolished. The new ballot law required the use of a modified Massachusetts ballot on which the first place in each office group was to be given to the candidate of the party which received the largest number of votes in the preceding election for governor. The party emblem was permitted. The workmen's compensation law was made to cover specified hazardous employments. It fixed rates and periods of compensation. A state workmen's compensation commission of five members appointed by the governor was created.

The 1914 Legislature enacted an optional charter law for cities of the second class (with pop. between 50,000 and 175,000) and of the third class (with pop. below 50,000). Among the seven types of charters authorized were those providing for the city manager and the commission. In accordance with a law enacted in Dec. 1913, an election was held April 7 1914 to determine whether a state constitutional convention should be called. Less than one-fifth of the qualified voters participated in the election, but of these a small majority favoured a convention.

In the autumn elections of 1914 the Republican party was successful. The vote for governor was: Whitman, Republican, 686,701; Glynn, Democrat, 541,269. The new Legislature was strongly Republican in both branches. Of the delegates to the Constitutional Convention, 116 were Republicans, 52 Democrats.

The new Legislature passed a widowed mothers' pension law providing for the creation of county boards of child welfare, with authority to grant allowances to widowed mothers with dependent children under 16 years of age. The inferior criminal courts of New York City were reorganized and a board of city magistrates with one chief magistrate was created. The law gave a magistrate the right to sit as a judge of Special Sessions and to dispose summarily of minor misdemeanours. Another law authorized parole commissions in cities of the first class (with pop. of 175,000).

The outstanding event of 1915 was the Constitutional Convention, which met at Albany on April 6 and lasted until Sept. 10. Elihu Root was chosen president. Although the proposed new constitution embodied many highly desirable reforms it was overwhelmingly rejected by the voters at the Nov. election. The vote was: for the constitution, 400,423; against, 910,462. Two amendments, relating to legislative apportionment and to

taxation, were likewise defeated. The woman suffrage amendment proposed by the Legislature failed by almost 200,000 votes. The new Assembly was strongly Republican.

The Legislature of 1916 established a military training commission to coöperate with the State Board of Regents in regard to physical training for pupils in elementary and secondary schools, and to give military training to boys between the ages of 16 and 19 during the school or college year. The Sage-Maier budget bill provided for a legislative budget. The Finance Committee of the Senate and the Ways and Means Committee of the Assembly were required, by the new law, to submit to the Legislature, not later than March 15, a detailed budget. The two committees were authorized to sit continuously and to appoint sub-committees to gather the data needed in the preparation of the financial programme. This work actually devolved on the clerks of the two committees. The Legislature passed also the Whitney-Brereton resolution providing for the submission of a woman suffrage amendment in 1917.

In Nov. 1916 Gov. Whitman was reëlected. He received 835,820 votes as against 686,862 for Judge Seabury, Democrat. For president, the Republicans carried the state, Hughes receiving 869,066 votes as against 759,462 for President Wilson. The New York Legislature was strongly Republican in both Houses. The legislation of 1917 and 1918 was influenced decidedly by the entrance of the United States into the World War. On the governor's advice, the Legislature enacted a compulsory military training law for boys between the ages of 16 and 19. School-children were allowed to work on farms between April 1 and Nov. 1. A state constabulary was created; and, under authorization of law, a census and an inventory of the military resources of the state were taken. The governor was empowered to require the registration of aliens. Numerous changes were made in the public-health laws of the state. The Legislature accepted for the second time the woman suffrage amendment. In the autumn election 703,129 votes were cast for the amendment and 600,776 against it. Another amendment, providing that debts incurred by any first-class city for water-supply purposes shall not be included in determining the debt limit, was likewise approved. This amendment extended to Buffalo and Rochester, an exemption previously enjoyed by New York City alone.

The 1918 Legislature was in session from Jan. 2 to April 13. A considerable number of war-emergency measures were adopted.

It was made a felony to injure or destroy military stores. A compulsory work law, applicable to able-bodied men between the ages of 18 and 50, was passed. The Food Commission established in 1917 was authorized to limit the margin of profits in retail sales of the necessaries of life. Contracts for the building of state and county highways were suspended for the period of the war. Teachers in the public schools were required to be citizens, and text-books containing seditious or disloyal statements were excluded from the schools. Absentee voting by those in the army and navy was authorized. The provisions of the workmen's compensation law were extended to cover practically all employments except farming and domestic service. A Central Supply Committee was created to make purchases for state departments, boards, and commissions. The Legislature partly repealed the "pay-as-you-go" law enacted in 1916, which made necessary the financing of all non-revenue-producing improvements in New York City through the annual tax levies, by the passage of a law allowing the city to issue annually during the war and one year thereafter $15,000,000 of bonds for certain kinds of improvements. A law provided for the enrolment and registration of women to participate in the 1918 elections. The Federal prohibition amendment failed of ratification.

In the Sept. primaries, 1918, Gov. Whitman was renominated for a third term. Alfred E. Smith, president of the New York City Board of Aldermen, was his Democratic opponent. Smith received 1,009,936 votes; Whitman, 956,034. The Republicans elected the other state officers except the lieutenant-governor. The Legislature remained Republican. In his message to the Legislature, Gov. Smith recommended important social and welfare legislation, most of which failed of passage because of the hostility of the Republican Legislature. The governor advocated health insurance, the minimum wage, and the eight-hour day for women and minors.

Several highly important laws were enacted. The income tax law provided for a tax of 1% on incomes up to $10,000; 2% on incomes up to $50,000; and 3% on incomes of over $50,000. Single persons were exempt up to 1,000; and married persons up to $2,000. An additional exemption of $200 was allowed for each dependent. The salaries of school-teachers were increased. An appropriation of $1,000,000 was made toward the building of the proposed New York-New Jersey vehicular tunnel. The employment of women on city railways was restricted. Children under 16 years of age were prohibited from working in factories longer than 48 hours in any one week. The Public Service Commission with jurisdiction over New York City was abolished and two new commissions were established in its place. One commissioner was given the regulatory functions of the former commission. The rapid transit construction work was transferred to a transit construction commissioner. The Legislature ratified the Federal prohibition amendment.

Shortly after his inauguration, Gov. Smith appointed a non-partisan Reconstruction Commission to inquire into and report on retrenchment and reorganization in the state government. This commission in its report of Oct. 10 1919 recommended an executive budget and the reorganization of the administrative departments of the state, following closely the proposals of the 1915 Constitutional Convention. The 1920 session of the Legislature devoted itself largely to the suppression of radicalism. It expelled five Socialist members of the Assembly and enacted a number of repressive measures designed to curb "revolutionists." These provided for the licensing of schools and school courses; additional certificates of loyalty from teachers; and machinery for testing the eligibility of members of the Legislature. All these measures were vetoed by Gov. Smith.

The most constructive work of the session was the passage of a number of bills designed to relieve the rent situation. The more important of these laws prevented the recovery of premises by landlords from "hold over" tenants until Nov. 1 1922, except where the tenants were objectionable, the premises were needed as residences by the owners, or the owners were desirous of putting up new buildings. It was also provided that in proceedings for the non-payment of rent, where the rent had been raised, the tenant might defend on the ground that the new rent was excessive. In such cases the landlord was required to file a bill of particulars showing the reasonableness of the increase. The courts were to pass upon reasonableness. It was further made a misdemeanour not to furnish normal service. The Legislature made additional appropriations for the New York-New Jersey tunnel. The salaries of school-teachers throughout the state were substantially increased.

The Republicans carried the elections in 1920 by overwhelming majorities. The vote for president was Harding, Republican, 1,868,240; Cox, Democrat, 781,485; Debs, Socialist, 203,400. The Republican candidate for governor, Judge Nathan L. Miller, was elected by a plurality of less than 75,000. Gov. Smith, his opponent, ran almost 500,000 votes ahead of the national Democratic ticket. The state Legislature for 1921 contained large Republican majorities in both Houses. The voters by a large majority approved a bond issue of $45,000,000 for a bonus to soldiers and sailors in the World War.

Gov. Miller, in his message to the 1921 Legislature, dealt chiefly with finance, urging rigid economy, and opposing the creation of new positions and salary increases. He favoured the completion of authorized construction projects before undertaking others. Later the governor sent a special message to the Legislature in which he outlined a programme for the reorganization of the Public Service Commission and the solution of the traffic problem in New York City. He recommended that all public utilities be placed under the jurisdiction of one state commission, except that a commission of three be established with complete jurisdiction over the one subject of transit in New York City. The Legislature passed measures carrying out the governor's recommendation. Other laws of importance, many of them sponsored by the governor, provided for the enforcement of the prohibition amendment directly by local police officers; the repeal of the daylight saving law; the return to the convention system of nominating state and judicial officers; the reorganization of the State Industrial Commission; the reorganization of the State Tax Commission and the transfer to it of most state tax-collecting agencies; the creation of a Board of Estimate and Control consisting of the governor or his agent, the chairmen of the Senate Finance and Assembly Ways and Means committees and the comptroller; and a treaty with New Jersey for the development of the port of New York. The anti-sedition laws adopted were designed to compel teachers to take an oath of loyalty and to empower the state Department of Education to license all private schools. Provision was made for a legislative investigation into the affairs of the New York City administration and for another to study the problem of charter revision in that city. Although the Republicans elected a majority of the members of the Assembly in the autumn elections of 1921, their strength was materially reduced by Democratic gains.

*The World War.*—New York led the states in the number of troops supplied for the World War. The total number from the

state (including Regular Army, National Army, National Guard, navy, Marine Corps, Coast Guard, and U.S. Guards) was 493,892, or 10·37% of the total. The number of casualties was 40,222. The subscriptions to the Liberty and Victory loans in New York State were: First Liberty Loan, $1,112,389,700; Second, $1,413,107,150; Third, $985,559,600; Fourth, $1,826,448,250; Victory Loan, $1,607,199,250; total $6,944,703,950. (E. D. G.)

**NEW YORK (CITY)** (*see* 10.610).—The pop. of New York City in 1920 was 5,620,048, as against 4,766,883 in 1910, an increase of 853,165, or 17·9%. The pop. of the separate boroughs was: Manhattan, 2,284,103 (in 1910, 2,331,542); Bronx, 732,016 (in 1910, 430,980); Brooklyn, 2,018,356 (in 1910, 1,634,351); Queens, 469,042 (in 1910, 284,041); Richmond, 116,531 (in 1910, 85,969). There were 5,450,004 whites, 153,088 negroes, and 7,956 others (Chinese, Japanese and Indians). The figures for 1910 were 4,669,162 whites, 91,709 negroes and 6,012 others. The white pop. constituted 97·1% in 1920 and 98% in 1910, while the negro pop. constituted 2·7% in 1920 and 1·9% in 1910. The increase in the white pop. since 1910 was 789,842, or 16·9%, while the corresponding increase in the negro pop. was 61,379, or 66·9%. The total foreign-born white pop. in 1920 was 1,089,216, as compared with 1,927,603 in 1910, an increase of 61,603, or 3·2%. The numerical increase was less than 10% of that of the preceding decade. Foreign countries furnishing the greatest number were Russia, 479,481; Italy, 388,427; Ireland, 202,833; Germany, 193,558; Poland (for the first time listed separately), 145,257; and Austria, 126,447. Of the total pop. in 1920 the males numbered 2,804,884, or 49·9%, and the females 2,815,164, or 50·1%. For the entire borough of Manhattan the average density was 162·5 inhabitants per ac., but in the Fourth Assembly District on the lower E. side (245 ac.) in which a great proportion was foreign born, the density was 420·3 per acre. In 775 tenement blocks in 1920 the density was over 1,000, the maximum being 3,869. In spite of overcrowding the city was healthy; for 1919 the average death-rate was 12·39 per 1,000.

The most important enlargements of public services provided since 1909 are the addition of the Catskill water to the city system, and the additions to the rapid transit system.

The Catskill system, secured by developing the Esopus watershed, was put in service in May 1917. It furnished a supply estimated to yield a minimum of 300 million gal. per day and with normal rainfall 325 million. Even before this the increased consumption of water had necessitated the undertaking of the development of the Schoharie watershed in 1916. This source, which is expected to be available in 1926, will provide an additional 300 million gal. per day, making a total normal supply at that time of 1,170 million gal. per day. The consumption of water is increasing so fast that, in view of the inevitable growth, the city already faces the problem of securing additional sources of supply. In April 1921, Blackwell's Island—the seat of the City hospital and of the Metropolitan hospital, as well as of the N.Y. County Penitentiary and of the Corrections hospital—was renamed Welfare Island, by the Board of Aldermen.

*Rapid Transit Development.*—As a means of meeting the demand for additional rapid transit facilities, the city by the Public Service Commission for the First District in March 1913 entered into separate contracts with the Interborough Transit Co. and the N.Y. Municipal Railway Corp. for the construction, equipment, and operation of a system of rapid transit lines known as the dual system. At this time the Interborough Rapid Transit Co. operated the subway lines in Manhattan, Bronx and Brooklyn, and under lease the elevated lines owned by the Manhattan Railway Co., *i.e.* the Second Ave., the Third Ave., and the Ninth Ave. lines, the last including the Sixth Ave. The N.Y. Municipal Railway Corp. was formed in the interest of the Brooklyn Rapid Transit Co. for the operation of various lines constructed or to be constructed as outlined in the dual plan. The N.Y. Railway Co., which operates most of the surface lines in Manhattan and the Bronx, is the only large traction system not included in the dual system. The operating contracts made with each company run for a period of 49 years from Jan. 1 1917, at the end of which time all leases and agreements will terminate and the city will have complete ownership and control over the constructions included in the dual plan. Provision is made in the contract for the sharing of profits with the city after the operating company has paid all necessary expenses and taken out an amount designated as a preferential, which represents an average of past earnings on old lines over a period of years. The contracts also specify that in the territory allotted to each company the rate of fare for a continuous ride shall be five cents. The dual plan provided for the construction of 322 m. of new track, making the total mileage of the completed system 618·7. While the plan as outlined approximately doubled the existing mileage it tripled the facilities then available, as the third tracking and extension of existing elevated railways materially increased the carrying capacity. For the Interborough these extensions comprised subway construction N. and S. of 42nd St., Manhattan. North of 42nd St. the new subway extended up Lexington Ave. and connected with the existing Fourth Ave. subway. New subway construction S. of Times Square extended the W. side subway down Seventh Ave. to lower Manhattan and by tunnel under the East river to Brooklyn. This construction provided independent through N. and S. rapid transit lines for the E. and W. sides of Manhattan Island. The addition of a third track and extension of existing elevated lines brought the added mileage to 167·7, a total for the Interborough system of 358·7. The main feature of the extension of the lines of the N.Y. Municipal Railway Corp. was the subway beginning at the Queensboro' Bridge and extending W. by 59th and 60th Sts. to Seventh Ave., thence S. by Seventh Ave., Broadway, Vesey St., Church St. and Trinity Place to a connexion with a tunnel under the East river at Whitehall St. This construction and other extensions make a total for New York of 105 m. and a total for the N.Y. Municipal Railway system of 260 miles.

At the end of 1920 all but 2·2 m. of the Interborough system and 15·3 of the N.Y. Municipal Railway system was completed. A continuous ride of 26·63 m. for five cents then became available on the Interborough system and one of 18·5 m. for the same fare on the Brooklyn lines. The anticipated cost of constructing the new lines provided under the Dual plan amounted to $337,000,000, which was to be distributed as follows: City of New York, $171,000,000; Interborough Rapid Transit Co., $105,000,000; N.Y. Municipal Railway Corp., $61,000,000; in addition to the above the city had already invested about $56,000,000 in the construction of the Fourth Ave. subway, and the Interborough Rapid Transit Co. had expended about $48,000,000 for the equipment of the line. Up to Jan. 1 1921 expenditures by the city and the operating companies amounted to approximately $435,000,000, including sums to be paid for work completed or nearing completion. Of this amount the city's part was about $214,000,000, the operating companies' $221,000,000. It was anticipated that the system when completed would be able to carry more than three billion passengers per annum. During the year ending June 30 1920 there were carried 2,364,775,067 passengers. The main rapid transit lines were operating in 1921 to the point of saturation and the situation demanded immediate provision for additional facilities.

*Manufactures.*—The N.Y. City Metropolitan District (a district of 616,928 ac. including in addition to New York City the neighbouring cities and towns both in New York State and New Jersey) is by far the largest industrial district in the United States, more than one-seventh of the entire industrial productions of the United States being credited to it. In 1914 it had 36,410 manufacturing establishments; these gave employment to an average of 1,031,815 persons during the year, 842,103 being wage-earners, and paid out $711,085,669 in salaries and wages. The value of the manufactured products was $3,428,223,150, the materials utilized $1,984,842,079, the value added by manufacture $1,443,381,071. The district represented 12·5% of the persons employed, 11·5% of the capital and 14·1% of the value of products for the whole country. Clothing ranked first with a value (1914) of $546,682,000. Printing and publishing, with products valued at $230,961,000, ranked second. Smelting and refining of copper, with a value of $207,752,000, ranked third, yet it listed but five establishments while clothing listed 6,229 and printing and publishing 3,647. The boroughs of Manhattan and the Bronx produced in 1914 goods valued at $1,577,852,000, or more than two-thirds of the total.

*Port of New York—Commerce.*—The port of New York was in 1921 in many respects the most important in the world. The value of the imports received increased from $891,614,678 in 1909 to a total of over $2,064,654,000 in 1919, or 131·6%. The value of exports in 1919 exceeded $3,456,329,000 as compared with $627,782,767 in 1909, an increase of $2,728,546,233, or 435%. The vessel tonnage entering and clearing during 1919 aggregated 15,049,000 and 14,275,000 tons, respectively. These totals far exceeded the commerce handled through any other port in the world. The increase in port facilities has by no means kept pace with the growth of business. Such improvements as have been completed during the years 1909–19 inclusive have been limited to more or less haphazard development work carried out under the supervision of the U.S. Government, the completion of the N.Y. State Barge Canal, and the execution of a limited number of enterprises by the city, providing additional docking and wharfage facilities. Among the more important of the projects carried out by the Federal Government are the East river improvement work and the completion of the Ambrose Channel. The East river improvement includes extensive dredging to provide a channel 40 ft. in depth between the Upper Bay and Brooklyn Navy Yard, and also through Hell Gate. Work done before 1921 comprised not alone dredging, but also the removal of reefs and ledge rocks, notably Coenties Reef and Shell Reef which had been a menace to shipping and restricted the development of an important part of the port. Expenditures on these improvements have aggregated $8,172,734, and it is antici-

pated that $6,350,000 additional will be required to complete the work. The most marked effect of this improvement will be to enable ships with a draught of 40 ft. to unload and take on cargoes at the piers instead of from lighters, and ultimately to follow the shorter and safer inside route through Long Island Sound in approaching or leaving N.Y. harbour. In 1914 the dredging and construction work incidental to the widening of the Ambrose Channel was completed. This waterway extends in a general N.W. direction from deep-water through the Lower Bay. It provides a channel about 7 m. in length, 2,000 ft. in width, with a depth of 40 ft. at mean low-water, and is the ordinary route taken by large vessels whose destination is N.Y. harbour. The Erie Canal has been improved and reconstructed at a cost to 1921 of over $154,500,000. It is popularly known together with various extensions and improvements as the N.Y. State Barge Canal. A greatly increased traffic is expected from it and elaborate terminal plans for N.Y. harbour were under way in 1921.

Notable port development projects carried out by the City of New York since 1909 include the following: North river—Improvement of water-front between 42nd St. and 59th St., involving the construction of four passenger steamship piers each 1,000 ft. long and with a dock area of 797,904 sq. ft. Only one of the piers had been built by 1921. East river—Three new city piers located at the foot of 29th, 30th and 35th Sts. respectively, South Brooklyn, were completed during 1916. These piers add 9,380 ft. of wharfage space and 568,500 sq. ft. of dock space to the city's dock properties. They form part of a logical plan of port organization which assigns to the Brooklyn water-front the heavier cargo business. Upper Bay—In 1918 the city initiated a project involving the development of the water-front of Staten Is., near Stapleton, by the construction of 12 large piers. This location afforded opportunity for the construction of piers over 1,000 ft. in length if desired with a natural depth of more than 40 ft. at the pier-head line. Also for the first time the city had the chance to effect track railhead connexions between its piers and all but two of the railways entering the port of New York, and to construct terminal warehouse and industrial plants in connexion therewith. The question at first arose as to whether the steamship companies would lease piers so far from the centre of commercial activity on Manhattan Island. Then the city laid down the policy that the moneys necessary to carry out the proposed improvement would only be appropriated when the dock commissioner secured leases from responsible lessees for the proposed piers at a rental equal to 7½% of the total cost of acquiring the land and lands under water and of making the improvement. In July 1919 11 duly executed leases, each accompanied by a bond, for a term of 10 years with two renewals of 10 years each were presented to and approved by the commissioners of the sinking fund, it being determined at the same time to build a twelfth pier and maintain the same for public wharfage.

These piers will be built in accordance with the particular requirements of the respective lessees. They will range in length from 1,000 to 1,160 ft.; eight are to be 125 ft. in width and covered by single-story steel freight-sheds with railway tracks down the middle of the pier; two will be 130 ft. in width and covered by two-story steel freight-sheds with railway tracks; two will be 209 ft. in width including side platforms equipped with railway tracks and a complete mechanical installation such as cranes, monorail cars, etc., together with elevators for transfer of motor-trucks to the second deck. On the upland in rear of the piers will be laid out comprehensive terminal facilities with ample tracks for storing an adequate number of freight-cars. It is estimated that this Staten I. improvement will cost upward of $25,000,000, of which $18,000,000 will be for pier and shed construction; it will provide more steamship wharfage than any other one improvement undertaken by the city. When this is finished, Richmond will have more wharfage facilities for overseas steamships than are in use at present for similar purposes on the entire island of Manhattan.

One of the main causes that have militated against a comprehensive development of the port of New York is the division that exists with respect to the water-front included within the limit of New York State and that within the adjoining state of New Jersey. The situation is further complicated by the fact that of all the railways entering the port only three have direct rail connexion with New York City: the New York Central in Manhattan, the New York, New Haven and Hartford in Manhattan and Queens, and the Baltimore and Ohio in the borough of Richmond. All other railways have their freight terminals on the New Jersey shore. The need for remedying this condition has long been recognized and in 1917, pursuant to concurrent legislation by the two states, the governor of each appointed a commission of three members to recommend jointly a policy to be pursued by the state of New York, the state of New Jersey and the United States, in the development of the port. The legal problem was unique on account of the dual state sovereignty involved. This necessitated the adoption by both states of a treaty as a prerequisite to undertaking any comprehensive plan of development. The recommendation of the joint commission was embodied in a statute introduced in the Legislatures of the two states. The statute was passed by the N.J. Legislature in 1920 and by the N.Y. Legislature in April 1921.

*Communications.*—Two important enterprises in providing additional direct lines of communication with New York City are the N.Y. connecting railroad across the East river and the proposed vehicular tunnel under the North river. The N.Y. connecting railroad provides direct rail connexion with the New York, New Haven and Hartford line for the boroughs of Queens and Brooklyn. The main features include a reinforced concrete arch viaduct extending from the connexion with the New York, New Haven and Hartford railroad in the Bronx to a point on Wards I., in the East river, a steel arch spanning that section of the East river known as Hell Gate, and connecting with a similar reinforced concrete viaduct in the Astoria section of Queensboro'. Surface construction provides direct passenger rail connexion with the Sunnyside Yard of the Long I. railroad and thence access to the Pennsylvania railroad terminal in Manhattan, while another branch for freight only extends to the Bay Ridge section on the water-front of South Brooklyn. The entire length of the connecting railway is 12 miles. The total amount expended was approximately $30,000,000. The bridge itself, the largest steel arch in the world, cost $18,000,000. Its massive granite piers rise to a height of 240 ft. and are 2,000 ft. apart. The steel arches which support the dock of the bridge rise 300 ft. above the water and the clearance for vessels at mean high-water is 140 feet. The bridge carries four tracks, two of which are used for passenger service as well as for freight.

The vehicular tunnel under the North river which when completed will connect Manhattan I. with Jersey City, is designed to provide a means of handling the traffic now forced to use ferries. Its construction was undertaken under the joint jurisdiction of the N.Y. Interstate Bridge and Terminal Commission and the N.J. Interstate Bridge Commission in accordance with the terms of a contract entered into by the two states Dec. 30 1919. The tunnel section includes twin tubes of cast iron 29 ft. in external diameter. The mean length of the cast-iron ring is 7,345 ft. while the distance between grade points is 9,300 ft. Each tube will have a 20 ft. roadway with an overhead clearance of 13 ft. 6 in. The N. tube is to be used for west-bound traffic, the S. tube for east-bound. The estimated yearly traffic in 1924, the date when it is anticipated the tunnel will be put in service, is approximately 5,610,000 vehicles. This is about equal to the traffic over the Williamsburg bridge across the East river during 1920. In 1934 it is estimated that the traffic demand will reach 12,900,000 vehicles annually. The anticipated total cost of the improvement is $28,669,000. It is estimated that the average charge for motor vehicles using the tunnel for the first 20 years will be 45 cents and for horse-drawn vehicles 20 cents. The revenues from the use of the tunnel on the above basis during that period would amortize the cost in 11 years and accumulate a surplus of $67,330,000, half to go to each state.

*Streets and Buildings.*—The construction of the new traction system involved some changes in the streets, the extension of Seventh Ave. being an example. The principal shopping district has shifted rapidly northwards, deserting in succession the 14th St. and 23rd St. sections. Its boundaries, broadly speaking, in 1921 were 31st St., Broadway, 59th St. and Madison Ave., and it was steadily continuing northward. The principal shopping streets were Broadway, 34th St., 42nd St. and 5th Avenue. Park Ave., N. from the Grand Central Station, was rapidly superseding Riverside Drive as the well-to-do apartment district, and there was a distinct movement of the finer residential section to the eastward, reaching in one instance as far as Ave. A.

Between 1909 and 1921 there was considerable addition to the number of the tall buildings, which made the sky-line of the city an impressive spectacle. The Woolworth Building (792 ft.) is the highest structure in the world excepting the Eiffel Tower. It is a remarkable example of the adaptation of the Gothic style to the "sky-scraper," is faced with cream-coloured, glazed terra-cotta and is crowned by a huge lantern, brilliant at night, under which is an observation gallery, from which on a clear day a 50-m. view may be obtained. Other notable new buildings are: The Bankers' Trust (539 ft.); Equitable (485 ft.); Adams Express (424 ft.); Whitehall (424 ft.); American Express (415 ft.); American Telephone and Telegraph (403 ft.); 112 Park Ave. (390 ft.); Liberty Tower or Hanover National Bank (385 ft.); American Bank Note (374 ft.); 201 Broadway (362 ft.); 60 Wall Street (346 ft.); Candler (341 ft.); Allied Printing Trades (340 ft.); 37 Wall Street (346 ft.); 80 Maiden Lane (315 ft.); Columbia Trust Co. (306 ft.); Sun (306 ft.); and Cunard (335 ft.). The newer hotels include the Pennsylvania, with its 2,200 rooms, the largest hotel in the world; the Commodore, with 2,000 rooms; the McAlpin, Biltmore, Chatham, Vanderbilt, Ritz-Carlton and Claridge. The Knickerbocker, Holland House and Manhattan, formerly three of the best-known hotels, have been converted into office buildings, as has Sherry's restaurant.

*Finance.*—The city's budget grew from $163,130,270.37 in 1910 to $345,530,039.77 in 1921. The assessed value of its taxable property, real and personal, grew from $7,416,837,499 in 1910 to $8,922,628,742 in 1920, when the real estate was valued at $8,626,122,557. The net funded debt in 1920 was $1,033,878,359, the gross bonded debt being $1,238,260,597. The floating debt was $42,350,400 and the sinking fund $204,382,238. Among the large items of the 1921 budget were $50,720,880 for education; $105,528,527 for redemption and interest of the city's debt; $10,029,222 for county purposes; $28,349,407 for police; $17,409,649 for borough governments; $17,033,082 for fire protection; $16,790,036 for street cleaning; $8,706,947 for water supply and public lighting; $8,146,850 for charitable institutions; $4,074,637 for parks; $14,592,413 for public welfare; $5,655,868 health; and $5,419,850 plant and structures.

*History.*—During the administration of Mayor Gaynor, which began in 1910, there arose an increased interest in administration on the part of the citizens. The mayor, known locally for certain whimsical characteristics, had gained a hold on popular sympathy as a result of his attempted assassination. Later he became ill, and while on a steamer to Europe, travelling to regain his health, died Sept. 10 1913. Adolph L. Kline (b. 1858), president of the Board of Aldermen, succeeded to the office for the remaining few months of the term. A fusion ticket led by John Purroy Mitchel (1879–1918), who had made an enviable record in public office as Commissioner of Accounts, Collector of the Port and president of the Board of Aldermen, easily defeated the Tammany ticket. Mitchel, but 35 years of age, undertook a complete reorganization of administration, and obtained remarkable results, making his mayoralty a period of unprecedented efficiency in the city's government. Of especial note were the improvements in police, street cleaning, charities and corrections, and the establishment of high standards and expert service in taxation, purchasing and the selection of personnel. Though admittedly efficient, economical and honest, this administration saw itself at the end of four years buried under the greatest majority for Tammany on record. The causes were many. Mayor Mitchel antagonized one powerful group after another; certain real estate interests by the "pay-as-you-go" plan of financing; the German group by his pro-Ally sympathies; a large manufacturing group by refusal to remove trade refuse free of charge; the upper W. side by the unfortunate W. side plan for removal of the New York Central surface tracks; the Catholic vote by his procedure regarding certain charities; the borough of Richmond by locating a garbage incinerator plant in that section; and Brooklyn by his rigid policy of centralization. The result was that John F. Hylan (b. 1868), a candidate from Brooklyn, led a complete Tammany ticket into office, with a platform of outspoken opposition to almost everything the Mitchel administration had done. Subsequently, however, upon the election of the president of the Board of Aldermen, Alfred E. Smith, to the governorship of the state, and the death in office of the president of the borough of Manhattan, Republicans were elected to the vacancies so created. Mayor Hylan's régime was marked by continual wrangling among the members of the Board of Estimate, resulting in many cases in distinct disturbance of administrative machinery. The outstanding features were the fight of the city against increased fares for the traction lines, the declaration of receiverships for practically all of the traction companies of the city except the Manhattan elevated and subways, the dissolution of the companies into a number of independent lines, the operation by the city of the Staten I. traction lines and the introduction of motor-bus lines by the city in competition with the traction systems.

Among the notable bequests to the Metropolitan Museum during recent years have been those of Francis L. Leland, $1,000,000; Joseph Pulitzer, $900,000; Benjamin Altman, collection of paintings, sculpture, Chinese porcelains, etc., with a fund for their care; William Henry Riggs, collection of arms and armour; Harris B. Dick, collections and funds over $1,000,000; Isaac D. Fletcher, collection of paintings and objects of art and fund over $3,400,000; and John Hoge, over $1,000,000. (R. B. F.)

**NEW ZEALAND** (*see* 19.624).—The pop. of the Dominion of New Zealand (exclusive of Maoris), as enumerated at the taking of the census, was as follows: 1911 (April 2) 1,008,468 (531,910 males, 476,558 females); 1916 (Oct. 15) 1,099,449 (551,775 males and 547,674 females). The 1916 figures were of course affected by war conditions. At the end of 1916 females were estimated to be in a majority for the first time in the history of the country, and the majority steadily grew until at the end of 1918 they were more than 24,000 ahead. But with the return of the troops the preponderance of males was restored, though not to the same degree as before. On Dec. 31 1920 the official estimate of the pop. (excluding Maoris) was 1,194,844, of whom 604,751 were males and 590,093 females. If the 49,776 Maoris and the 12,797 inhabitants of the Cook and other Pacific islands annexed to New Zealand be added, the grand total is 1,257,417.

The pop. of the principal cities on Dec. 31 1919 was estimated as follows, the bracketed figures indicating the totals if suburbs are included: Auckland 73,852 (144,646); Wellington 81,301 (100,898); Christchurch 61,104 (104,747); Dunedin 57,935 (72,084). The proportion of the pop. living in towns of over 1,000 inhabitants in 1878 was 31·47; the proportion living in towns of over 3,000 inhabitants in 1916 was 42·28.

In 1916 72·34% of the pop. was New Zealand born; 25·83 was born in the United Kingdom or other British territory; and only 1·70 was foreign-born, Germany and Austria-Hungary, with 0·27 and 0·22 respectively, taking the lead.

In 1916 the number of "race aliens" in the Dominion, *i.e.* persons not of European or Maori descent, was 3,204; of these 2,147 were Chinese, 459 Syrians and 181 Indians. In 1896, when the poll-tax on Chinese was increased from £10 to £100, they numbered 3,711, but since then the number had steadily declined till 1920, when the arrival of 476 Chinese and 174 Indians during the first six months of the year led to a drastic measure which, without relaxing existing restrictions, left the regulation of foreign immigration in the hands of the Government.

*Births and Deaths.*—The birth-rate fell from its maximum of 41·96 per 1,000 in 1878 to 25·12 in 1899, the lowest figure reached before the war. In 1913 it stood at 26·14, and the average of the next four years was 25·74; then followed a sharp drop to the lowest figures yet reached: 1918, 23·44; 1919, 21·54.

The decline in the birth-rate continues to be partly compensated by an abnormally low death-rate, which in 1912 reached its lowest recorded point of 8·87 per 1,000, and in 1919 was 9·51. Only once since 1907 has the rate been as high as 10 per 1,000, and that was in 1918, when the epidemic of pneumonic influenza caused 5,516 deaths (exclusive of approximately 1,200 among the Maoris) and brought the death-rate up to 14·84. The effect of the low death-rate is to give the Dominion one of the highest rates of natural increase in the world, the figures for 1913–7 being 16·4 per 1,000.

The death-rate per 10,000 from the four principal causes during 1919 was as follows: organic heart disease 13·53; senility 9·29; cancer 8·23; pulmonary tuberculosis 5·30. The averages for the two last-named causes during the ten years 1910–9 were: cancer 8·23; pulmonary tuberculosis 5·58. The death-rate for all forms of tuberculosis has been declining for many years, but that from cancer is steadily rising.

*Trade.*—External trade rose from £37,372,000 in 1907 to £45,275,024 in 1913. In "special" trade per inhabitant New Zealand with £41 14s. 3d. was in that year second to Belgium alone (£48 18s. 1d.), and in exports of domestic produce (£21 3s. 8d.) she stood first. The course of the Dominion's trade during and since the war is shown by the following figures:—

| | Imports | Exports | Total |
|---|---|---|---|
| 1913 | £22,288,302 | £22,986,722 | £45,275,024 |
| 1914 | 21,856,096 | 26,261,447 | 48,117,543 |
| 1915 | 21,728,834 | 31,748,912 | 53,477,746 |
| 1916 | 26,339,283 | 33,286,937 | 59,626,220 |
| 1917 | 20,919,265 | 31,587,547 | 52,516,812 |
| 1918 | 24,234,007 | 28,516,188 | 52,750,195 |
| 1919 | 30,671,698 | 53,970,075 | 84,641,773 |
| 1920 | 61,595,828 | 46,441,946 | 108,037,774 |
| 1921* | 15,658,502 | 13,196,514 | 28,855,016 |

*March quarter.

The favourable balance of trade, which had averaged a little over £2,000,000 in the five years before the war, averaged in 1915–9 £11,043,314. It increased to £23,298,467 in 1919, but the adverse balance of £15,153,882 in 1920, when the previous year's "record" imports were doubled, combined with the fall in the price of wool and meat, indicates a severe check to the prosperity of the war period.

On ten principal exports, representing in value more than 80% of the whole, it is estimated that in the four years ended March 31 1919 the Dominion gained £34,410,144 through the appreciation of its produce since 1913, the proportion being 45·98 per cent.

During the years 1909–13 the United Kingdom supplied 60·07% of the Dominion's imports and received 80·43% of its exports. The contributions of the British Empire were 83·87% of the imports and

94·35% of the exports. Foreign countries supplied 16·13% of the imports and took 5·65% of the exports, the United States coming first with 8·80% and 3·04% respectively, and Germany second with 2·66% and 0·99% respectively.

In the five years covering the World War (1914–8) the United Kingdom took 77·94% of the Dominion's exports, other British possessions 10·43%, and foreign countries 11·63%. The imports, classified according to the countries of origin (shipment figures alone being previously available), were contributed as follows: United Kingdom 46·60%; British Empire 72·54%; foreign countries 27·36%.[1] The United States and Japan are the two foreign countries with which trade developed most rapidly during the war. The exports to the United States, which amounted to £714,063 in 1907 and £912,051 in 1913, rose to £2,006,507 in 1915, £4,045,648 in 1918 and £4,200,861 in 1919. The Dominion's imports from the United States during the same years were: 1907 £1,425,596; 1913 £2,107,990; 1915 £2,600,248; 1918 £4,980,748; 1919 £7,576,314. The United States in 1919 supplied 26·3% of the imports and in 1918 took more than 14% of the exports. The Dominion's imports from Japan increased from £151,106 in 1913 to £304,322 in 1915, £1,214,865 in 1918 and £1,313,205 in 1919; but this was due to war conditions.

*Production.*—The dependence of New Zealand's prosperity upon the pastoral industry shows no signs of being weakened by her progress in other directions. Though wool, which in 1897 formed 47·9% of the total value of the exports, provided not much more than a third in 1920, it was still the most important export; and its decline in relative importance was merely the result of the rapid development of other pastoral products. Between 1895 and 1914 the pastoral industry's contribution to the exports had actually increased from 70·3% to 85·8%, and in the best of the war years (1916) it went as high as 90·7%. The exports of dairy produce rose in these twenty years from £378,510 (57,964 cwt. butter and 76,743 cwt. cheese) in 1895 to £4,902,701 (434,067 cwt. butter and 863,776 cwt. cheese), or from 4½% to 19% of the total, the actual increase in value being 1,198%. The increase of frozen meat in the same period from £1,262,711 (1,134,097 cwt.) to £5,863,062 (3,229,869 cwt.), a rise in value of 364%, is proportionately a small matter. The following table shows the advance of the chief pastoral products:—

*Exports of Pastoral Produce.*

| Year | Wool | Frozen Meat | Butter | Cheese | Skins, Hides, Pelts, Tallow, etc. |
|---|---|---|---|---|---|
| | £ | £ | £ | £ | £ |
| 1895 | 3,662,131 | 1,262,711 | 227,601 | 150,909 | 534,993 |
| 1900 | 4,749,196 | 2,123,881 | 740,620 | 229,111 | 732,260 |
| 1905 | 5,381,333 | 2,694,432 | 1,408,557 | 205,171 | 1,023,087 |
| 1910 | 8,308,410 | 3,850,777 | 1,811,975 | 1,195,373 | 1,885,882 |
| 1914 | 9,318,114 | 5,863,662 | 2,338,576 | 2,564,125 | 2,011,941 |
| 1915 | 10,387,875 | 7,794,395 | 2,700,625 | 2,730,211 | 2,231,104 |
| 1916 | 12,386,074 | 7,271,318 | 2,632,293 | 3,314,310 | 2,453,018 |
| 1917 | 12,175,366 | 5,982,404 | 2,031,551 | 3,949,251 | 2,414,833 |
| 1918 | 7,547,266 | 4,957,576 | 3,402,223 | 4,087,278 | 3,493,482 |
| 1919 | 19,559,537 | 9,628,292 | 3,080,128 | 7,790,990 | 6,119,474 |
| 1920 | 11,863,827 | 11,612,829 | 3,022,335 | 6,160,840 | 4,064,445 |

There were 25,828,554 sheep in the Dominion in 1919 and 3,035,478 cattle, of which 863,588 were kept for dairying purposes; 2,409,214 cattle and 14,211,944 sheep were in the North Island.

Of the total area of land in occupation in 1919–20 (43,473,079 ac.) 18,004,776 ac. were in cultivation, 16,125,265 being in English grasses. In agriculture the Dominion does little more in normal years than provide for its own needs. During the years 1919–9 agricultural produce only averaged 1·77 per cent. of the exports. The acreages and yields of the principal crops in 1919–20 were: Wheat 139,611 ac., 4,559,934 bus. (32·66 per acre); oats 179,800 ac., 6,967,862 bus. (38·75 per acre); potatoes 24,933 ac., 144,705 tons (5·79 per acre). During the years 1910–20 the area in wheat averaged 230,070 ac., with a yield per acre of 28·02 bus. and a production of 5·82 bus. per head of population. In the years when production falls below 6 bus. per head importation is necessary, usually from Australia.

*Mining.*—The gold industry, which fifty and sixty years ago supplied more than half the colony's exports, is of small importance now. The quantity and value of the export were as follows in the years named: 1866, 735,080 oz., £2,844,000; 1906, 363,843 oz., £2,270,904; 1916, 192,620 oz., £1,199,212; 1920, 212,073 oz., £883,748. The proved coal resources of the Dominion (610,000,000 tons) are estimated to last about a century. The output during the years 1900–10 rose by fairly regular increments from about 1,000,000 to about 2,000,000 tons. The maximum of 2,257,135 tons was reached in 1916, but since then there has been a steady decline to 1,847,848 tons in 1919. This decrease, which originated in a labour shortage arising from the war, was continued by the miners' "go-slow" policy, and but for special importations the stoppage of many important industries would have resulted. The local supply has always been supplemented by imported coal, chiefly Australian, averaging about 300,000 tons a year, or one-seventh of the total consumption in the years 1909–13. In 1919 and 1920 imports of 391,434 tons and 476,343 tons respectively relieved the local shortage. S. Africa provided a small part of this supply, and in 1921 the Government let a contract in South Wales.

*Hydro-Electric Power.*—New Zealand is well endowed with water-power, 23 sources of supply in excess of 1,000 H.P. being enumerated in the North Island and 46 in the South Island. Little use had been made of this asset before 1900, but the actual horse-power in use in 1912 was 18,353. This had increased to 43,016 by March 31 1915, the total in 1920 being 47,983 horse-power.

The main sources of supply selected for the Government's North Island scheme are Mangahao in the Wellington District (24,000 H.P.); Arapuni, Auckland District (96,000 H.P., capable of extension to 162,000 H.P.), and Waikaremoana, Hawke's Bay (40,000 H.P., capable of extension to 136,000 H.P.), and work on the first of these was well in hand in 1920. The South Island has already the two largest of existing installations, but the outlines of the general scheme for the island had not been laid out. At Lake Coleridge in the Southern Alps, 65 m. west of Christchurch, the Government had erected a plant of a capacity of 8,000 H.P., and an ultimate extension to 58,000 H.P. will be possible. From this source the electric lighting and tramway systems of Christchurch and a large number of workshops and factories are supplied, and in addition to its far greater efficiency, the new method, by the saving of 45,000 tons of coal and other economies, is estimated to have saved £300,000 in the first five years of its working. A similar service is performed for the city of Dunedin by its city council's power station on the Waipori river 32 m. away.

The total capital outlay on electric-power supply up to March 31 1920 was £3,253,870. Loans totalling £1,980,000 had at that date been voted in five of the electric-power districts. The total cost of the Government's scheme will considerably exceed £20,000,000.

*Manufactures.*—Between the census of 1906 and 1916 the number of manufactories and works increased from 4,186 to 4,670; the number of hands employed from 56,359 (males 44,946; females 11,413) to 57,823 (males 43,970; females 13,853); the wages paid from £4,457,619 (males £3,979,593; females £478,026) to £6,654,504 (males £5,868,788; females £785,716); the value of all manufactures or produce (including repairs) from £23,444,235 to £45,454,184. By far the most important of these industries are the meat-freezing and meat-preserving works and the butter and cheese factories, which, with outputs valued in 1919 at £4,852,732 and £10,636,782 respectively, accounted between them for nearly half the aggregate value (£58,374,507). Most of the other manufactures are for local consumption only and could not exist without the help of the tariff. The increase in wages per head per annum was from £79 2s. (males £88 10s.; females £41 18s.) in 1906 to £133 16s. (males £139 8s.; females £68 16s.) in 1919.

*Land.*—The area of the Dominion, excluding the Cook and other islands annexed in 1901, is 66,292,232 ac., which from the standpoint of occupation and tenure was in 1919 broadly classified as follows:—

| | Acres |
|---|---|
| Private freehold | 19,255,874 |
| Public reserves, etc. | 13,591,041 |
| Crown lands leased, etc. | 19,411,473 |
| Crown lands undisposed of | 3,414,568 |
| Native land | 5,066,197 |
| Barren and worthless country | 3,307,515 |
| Roads, rivers, lakes, etc. | 2,245,584 |
| Total | 66,292,232 |

Noticeable features are the small area awaiting disposal by the Crown and the large area owned by the Maori people. During the last ten years 2,380,000 ac. of native land have been sold, over 1,000,000 ac. having been acquired by the Crown. Of the 5,000,000 ac. retained by the natives about 3,000,000 are leased, and much of the remainder is poor or worthless. The areas held from the Crown under the principal tenures on March 31 1920 were as follows: pastoral runs, 10,174,236 ac.; small grazing runs, 2,740,032 ac.; leases in perpetuity, 1,752,876 ac.; renewable leases, 1,744,903 ac.; occupation licences with right of purchase, 1,507,814 acres. The area resumed by the State for subdivision under the Land for Settlement scheme up to March 31 1920 was 1,891,011 ac., at a cost of £11,454,655; 6,167 selectors were holding a total of 1,631,163 ac., for which the annual rental was £462,941, and 160,395 ac. had been sold for cash or made freehold, the total purchase money being £397,169.

The unimproved value of the land of the Dominion on April 1 1920 was assessed for the North Island at £182,956,317; South Island £107,923,947; total £290,880,264. Capital value (including improvements): North Island, £302,178,759; South Island, £167,914,938; total, £470,093,697.

[1] The scope of the preferential tariff, which was established in 1903 and extended in 1907, was further extended in 1917. In 1919 the Imperial imports affected by the preference were valued at £19,519,619 and the foreign imports so affected at £11,152,079. The proportion of foreign imports affected was 21·37% in 1904 and 42·99% in 1919. The principle of the preferences is not the reduction of the duties on goods produced or manufactured in the British Dominions, but an increase of the duties on foreign goods.

*Education.*—The census of 1916 showed that 83·53% of the population were able to read and write, and 15·79% unable to do either. The expenditure on education from the public funds has increased rapidly in recent years, as the following figures show: 1898–9 £519,000; 1904–5 £679,000; 1913–4 £1,301,000; 1917–8 £1,814,000; 1918–9 £1,986,000; 1919–20 £2,544,000. The increase during these 21 years was from 13s. 4d. to 41s. 10d. per head.

The rapid increase had been due in part to the greater demands in all grades for free education, but chiefly to the provision of better salaries for teachers, the increased cost of maintaining buildings, and incidental expenditure. As the result of Acts passed in 1914, 1917 and 1918 respectively, the annual cost of State school teachers' salaries rose 66% in five years. The average salaries paid to these teachers in 1919, including house allowance or value of residence, were: Male head-teacher £380; female head-teacher £319; male assistant £301; female assistant £197; sole male teacher £221; sole female teacher £193.

The total number receiving instruction in 1919, excluding the pupils of private schools not inspected by the Education Department, was 255,320, made up as follows: Primary 218,174; secondary (including technical high schools) 16,084; technical and continuation (excluding technical high schools) 17,950; university colleges 3,060; Lincoln Agricultural College 52.

The average weekly roll of the State primary schools in 1919 was 193,658, with an average attendance of 90·3 per cent. Physical exercises based on the syllabus of the English Board of Education are practised in all these schools, with corrective classes for children with physical deformities. A staff of 10 school medical officers and 15 school nurses examine the children, notifying parents when medical or dental treatment is required. The number of schools visited in 1919 was 704, and about 30,000 children were completely examined. A director of school dental services has recently been appointed to superintend the treatment of dental defects and the training of children in the preservation of their teeth. A bureau of infant welfare, with Dr. Truby King as director, has also been established, with functions which include the supervision of the health and well-being of the children from birth until they enter school.

Of the 34 secondary schools 32 provide free places; the holders of these places in 1919 represented 94% of the roll number and cost the Government £111,000. The total number of pupils receiving free secondary instruction in 1919 was 12,620.

*Liquor Licensing.*—Local option was established in 1893, and from 1896 to 1914 inclusive the poll was taken triennially on the day of the general election in 76 licensing districts co-terminous with the parliamentary electorates. Thirteen of these districts are "dry," as the result of polls taken between 1894 and 1908 at which the three-fifths majority needed to carry no-licence was obtained. In 1910 Local Option was supplemented by National Option but a three-fifths vote was again made a condition of prohibition and its operation was to be postponed about 4½ years. The two national polls taken under these conditions resulted as follows: In 1911: Licence 205,661; Prohibition 259,943; proportion of prohibition vote to total, 55·83 per cent.; no proposal carried. In 1914: Licence 257,442; Prohibition 247,217; majority for Licence 10,225.

In 1918 the National Efficiency Board, which was appointed in 1917 to advise the Government on, *inter alia*, the enforcement of public and private economy and the promotion of national efficiency during the war, recommended total and immediate prohibition in the interest of national efficiency, but with compensation—a principle which had not been applied to the liquor trade before—for the abolition of the time-limit. The result was the Licensing Amendment Act 1918, which abolished local option and provided for a special poll on national prohibition with compensation in lieu of the time-limit, and for triennial polls thereafter on the three alternatives of licence, prohibition without compensation, and state purchase and control, the issue in each case being determined by an absolute majority of the votes cast. The two polls taken under this Act in 1919 resulted as follows: April: Licence 264,189, Prohibition with compensation 253,827; majority for licence 10,362. Dec.: Licence 241,251, State purchase and control 32,261, Prohibition 270,250. As none secured an absolute majority no change resulted.

Political History.—The closing years of the Liberal regime which had ruled New Zealand since 1891 were not distinguished by any of the daring experiments in social, industrial and agrarian legislation which had marked its opening years. The pace had indeed been too fierce to last. It had slackened long before the death of Seddon, the enterprising and all-powerful Liberal leader, in 1906, nor was it in the power of his successors to reverse the process. Most of those early experiments had justified themselves in the public estimation. The Liberal-Labour legislation was generally accepted, but new applications of its principles were not forthcoming in sufficient force to arouse either supporters or opponents to the enthusiasm with which the original measures had been advocated and attacked. The result of this slackening of Liberal enterprise, synchronizing with the removal of that masterful personality which for thirteen years did "bestride our narrow world like a Colossus," was that during the six years of Sir Joseph Ward's administration (1906–1912) politics became relatively tame and the old party lines less distinct, though many of the old catchwords survived. At the same time Labour, dissatisfied with the alliance with Liberalism which had for many years been so fruitful, and finding the Opposition still less to its liking, began to aspire to independence.

Among the legislative achievements of the Ward Ministry may be mentioned the Land Settlement Finance Act 1909, which enabled the Government to finance associations of private buyers in the purchase of freehold estates for subdivision and settlement; the Public Debt Extinction Act 1910, which provided for the creation of sinking funds for the extinction of the public debt in 75 years; the National Provident Fund Act 1910, which encouraged the provision of annuities in old age, with supplementary benefits for the protection of the family from birth to old age, by a voluntary scheme which the State was to subsidize to the extent of one-fourth of the contributions; the Licensing Amendment Act 1910, which amended the local-option legislation and supplemented it by providing for a poll on total prohibition for the whole Dominion on the day of the triennial general election; and the Widows' Pensions Act 1911, which granted to indigent widows an allowance for each child under the age of 14.

*Defence.*—But the most distinguished achievements of the Ward Government were the gift of a battle-cruiser to the navy and the introduction of compulsory military training. The speeches delivered on March 16 1909 by Mr. McKenna and Mr. Asquith in the debate on the navy estimates caused much anxiety in New Zealand because, as Sir Joseph Ward expressed it, "no room is left for doubt that England feels that her supremacy on the sea is seriously threatened by the amazing naval activity in the German dockyards." The offer was accepted, and the battle-cruiser "New Zealand," built at a cost to the Dominion of £1,701,000, received her commission on Oct. 12 1912.

The establishment of compulsory military training by the Defence Act 1909, though a more serious undertaking than the gift of a battle-cruiser, did not demand the same strong initiative on the part of the Government. A movement in favour of universal military training had been in progress for some time, but at the general election in Nov. 1908 it had failed to make any material impression. Even in June 1909, when Sir Joseph Ward left to attend the Defence Conference, its position was not strong, but on his return in Oct. it had gathered irresistible force, and by Dec. 24 the reform was on the statute-book. A well-organized platform campaign, which had exploited the German peril to the full and had received the powerful help of Mr. R. McNab, a leading member of the Ward Ministry before his defeat at the general election of 1908, had carried all before it. The Defence Act 1909 provided for the compulsory military training of all able-bodied males (*a*) from 12 to 14 years of age in the Junior Cadets; (*b*) from 15 to 18 years in the Senior Cadets; and (*c*) from 18 to 21 years in the General Training Section, from which transfers were to be made to the Territorial Force if voluntary recruiting failed to keep it up to the required strength.

In 1910 the Act was amended to make the scheme fit in with the recommendations of Lord Kitchener, who in that year visited Australia and New Zealand in order to report upon their defence systems. For Australia he recommended an army of 80,000 citizen soldiers between the ages of 18 and 25 years, and a reserve in which they would serve for an additional 5 years; and for New Zealand, to which the report was made applicable *mutatis mutandis*, the number would be about 20,000. The Defence Amendment Act 1910 accordingly extended the age-limit to 25 years, with a further period of 5 years in the reserve. The extension of the age-limit involved a cutting down of the universality of the scheme, as only about half of the number eligible was required. The minimum amount of training for the Territorials and Senior Cadets included 30 drills, 12 half-day or 6 whole-day parades, and 7 days in camp.

Sustained by a strong public enthusiasm which valued the

moral and physical even more highly than the military effects of the system, and tactfully guided by Maj.-Gen. (afterwards Lt.-Gen. Sir Alexander) Godley as commandant, the administration gave surprisingly little trouble; but the Ward Government, on the eve of the elections of 1911, showed less determination in the face of some recalcitrant defaulters than did either of the two succeeding Governments after the elections had passed. In 1913–4 the strength of the forces was: Permanent forces 578; Territorials 25,902; Senior Cadets 25,659. The expenditure on military defence was £519,294.

*Reform Movement.*—The general election of 1911 turned largely on questions of personnel and administration. The old Liberal-Labour enthusiasm had not been revived. Sir Joseph Ward, who had stated a few years before that a slackening of the pace of legislation was desirable, had no striking legislative programme to submit to the electors. The Opposition, which had lately adopted the name of Reform party, concerned itself chiefly with attacking the administration of the Government, especially in regard to partisan appointments to the public service and the Legislative Council and partisan dispensation of public works. For each of these alleged abuses the Reform party proposed a legislative remedy. They also proposed to concede to most of the Crown tenants the right to purchase the freehold—a proposal which appealed very strongly to the rural electors and took the Government at a disadvantage by dividing its followers. The Liberals were further embarrassed by the growing hostility of Labour. The independence which Labour had begun to display in Seddon's lifetime had steadily developed since, and now threatened the Government with more serious consequences by better organization, a more determined hostility, and a larger supply of Labour candidates. The alliance of small landowners and workers which had made the Liberal-Labour combination irresistible was thus threatened in both its branches.

The great weakening of the Government revealed by the polling of Dec. 7 1911 came nevertheless as a general surprise, the figures being: Government (Liberals) 37; Opposition (Reform party) 37; Labour 4; Independent 2. The new Parliament was summoned for a special session on Feb. 15 1912, and the no-confidence motion moved by Mr. W. F. Massey, the leader of the Opposition, was rejected on Feb. 27 by the casting vote of the Speaker, the voting being 39 to 39. Parliament was then prorogued, and, pursuant to a promise which he had given during the no-confidence debate, and which had saved the Government from defeat by inducing two of the Labour members to violate their election pledges, Sir Joseph Ward resigned the premiership. He also declined to take any other office. A new Liberal Ministry was formed by Mr. (afterwards Sir) Thomas Mackenzie, which included no member of the Ward Ministry except himself, but on the reassembly of Parliament it was defeated on the first test division by 41 votes to 33 (July 6). The Liberal regime which had ruled the country for 21 years without a break, and during the greater part of that time with an absoluteness which was good neither for the country nor for the party itself, was at an end. It was significant that three-fourths of the Opposition majority was accounted for by secession from the Government, who gave the land question as the reason for their change.

Mr. Massey was sent for and on July 10 the Mackenzie Ministry resigned, and the names of the new ministers with their principal portfolios were as follows: Mr. W. F. Massey, Prime Minister, Lands, Agriculture and Labour; Mr. (afterwards Sir) James Allen, Finance, Defence and Education; Mr. W. H. (afterwards Sir) William Herries, Railways and Native Affairs; Mr. (afterwards Sir) William Fraser, Public Works, Mines; Mr. A. L. Herdman, Attorney-General, and Justice M. B. Fisher, Customs and Marine; Mr. F. H. D. (afterwards Sir Francis) Bell, K. C., Internal Affairs and leader of the Legislative Council; Mr. R. H. (afterwards Sir Heaton) Rhodes, Postmaster-General and Public Health; Mr. Maui Pomare, Cook and other islands and member of Executive representing the native race. The new Ministry made good progress in its first session with the measures which the Reform party had promised on the hustings. The Public Service Act 1912 placed a large part of the service under the sole control of a Commissioner and two Assistant Commissioners to be appointed for the term of seven years, responsible only to Parliament, and removable only for misconduct or incompetence. A salutary restraint was placed upon the activity of the politicians by a clause which rendered anybody liable to a £50 fine who sought to interfere with the Commissioner's decision in regard to any appointment, promotion or dismissal, a principle which Sir Joseph Ward had in 1907 declared his willingness to accept in its application to members of Parliament. The completeness of the measure was seriously marred by the exclusion of the railways, one of the largest of the departments, from its operation. Another, the Post and Telegraph Department, was excluded in 1918 when the National Government was in office; but Mr. Massey afterwards declared the intention of the present Government to extend the scope of the Act. The measure certainly enhanced the independence of the service, as its members fully appreciated, and the Liberals, who strongly opposed the passing of the bill, appear to have accepted the principle. In a country where, according to the estimate made by a Liberal minister, Mr. J. A. Millar, as long ago as 1909, about one-eighth of the people are directly dependent on the State, the importance of this principle is obvious. No attempt has been made to deal with what the Reform party justly denounced to the electors as a much more powerful instrument of political influence—the ministerial control of Public Works, which in judicious hands may determine the votes of a whole countryside in favour of the Government. A measure of decentralization which will delegate much of this power to an improved local Government system seems to be the remedy required.

The reform of the Legislative Council was undertaken in 1912 in a drastic bill which was read a second time by the Council and then shelved. As finally passed two sessions later, after the Government had appointed new Councillors for the purpose, the Legislative Council Act 1914 provides for the popular election of a Council of 40 members—half the number of the members of the House. For the purposes of the Council election the 76 single-member electorates which elect the European members of the House will be grouped in 4 electoral divisions, 2 for each island, and each division will return its quota of Councillors under the Tasmanian system of proportional representation. The quota will be readjusted after each census in accordance with the population, but it will always be an odd number, and it is fixed for the present at 11 for the North Island divisions and 9 for those of the South Island. Though the Act was passed in 1914, it was not yet in operation in 1921. As it had sharply divided the parties, its suspension was made a condition of the war coalition, and in 1920 its operation was further postponed by an amending Act. Mr. Massey shared the widespread opinion that the power of nomination to the Council should not be entirely abolished. The measure never attracted any general enthusiasm, and the higher standard observed by the Reform Government in its nominations much weakened the case that the party made for a change in the law when in Opposition.

*Land Agitation.*—The land question, which had contributed more to the Reform party's success than any other legislative issue, was also dealt with during the Massey Government's first session. In 1907 Mr. R. McNab, who was then Minister of Lands in the Ward Government, had done good work by procuring the abolition of the "eternal lease." That a tenure which alienated Crown land for a 999-years' term on a 4-per-cent. rental without revaluation—thus seeking to settle the battle of the tenures by a compromise which combined the vices of both—should have remained on the statute-book during 15 restless years, is one of the wonders of New Zealand politics. Mr. McNab's Land Act substituted for this absurdity a perpetually renewable lease—a lease for 66 or 33 years, with a continuous right of renewal subject to revaluation, and gave the holders of existing perpetual leases the option of converting them into renewable leases or purchasing the freehold. The right of purchase, however, did not extend to "settlement land"—i.e.

land generally of an improved character, acquired by the Crown under the scheme for the purchase and subdivision of large estates. Mr. Massey's Land Act of 1912 extended the right to settlement land and also authorized the sale of any such land for cash, besides making the terms of the purchase more favourable to the tenants; but the 9,000,000 ac. set aside by Mr. McNab's Act as a national endowment for education and old-age pensions were not interfered with. A long-standing controversy was thus determined, and perhaps finally settled, in favour of the freehold. The attempt to make the retention of the fee-simple by the State a touchstone of Liberalism had never succeeded, and if the statesmen of an earlier generation who pioneered the proposal were here to-day they would doubtless admit that the political power of Crown tenants clamouring for concessions is a danger which their theories had overlooked. There is wisdom in the saying, "In time of trouble the State will look to the freeholder, but the leaseholder will look to the State." It is to taxation that the reformer must now look for the revenue which he had once hoped to get from rents and unearned increment.

*Labour Difficulties.*—Industrial troubles soon claimed the attention of the Massey Government. The Court of Arbitration was very popular with the workers during the first 11 or 12 years of its existence because, in a period of expanding industry, it rarely sent them away empty-handed. There were no strikes during those years (1894–1905), and only one in 1906, but in 1907 and 1908 the dissatisfaction of the workers found expression in 24 strikes and in denunciation of the Court as an ally of the capitalists. The power which the Court exercised of attaching the funds of a union guilty of promoting an illegal strike also led some of the unions to escape its jurisdiction by cancelling their registration as industrial unions under the Arbitration Act. This policy was encouraged by the New Zealand Federation of Labour, to which, under the banner of revolutionary socialism, a strong minority of militant unions, including those of the miners, seamen and waterside workers, was affiliated. The Miners' Union at Waihi was one of those which had cancelled their registration under the Arbitration Act, and in 1912 some 150 of its members, disliking the methods of the executive, seceded, formed a new Engine-drivers' and Winders' Union and applied to have it registered under the Act. The granting of the application was the signal for the members of the original union to "down tools." A strike which was unique among New Zealand strikes, both in its origin and in its duration (May 13–Nov. 30), resulted in complete defeat.

A much more formidable strike occurred in the following year. On Oct. 22 1913, as the result of a dispute arising from their sympathy with a grievance of the shipwrights, the Wellington Waterside Workers' Union struck. Under the conduct of the Federation of Labour the strike spread to most of the other ports, to the coastal and intercolonial shipping, and to the coalmines; but the attempt of the Federation to make the strike general had little effect except in Auckland. Both there and in Wellington the strikers seized the wharves, and for about ten days blocked the ports except to passenger traffic. It was the dramatic intervention of the farmers, many of whom were brought face to face with ruin by the stoppage of the export of their butter and cheese, that saved the position. In Wellington they supplied 1,000 mounted men, to act with the same number of special constables on foot, enrolled from the citizens, in recovering the wharves and restoring order. The farmers also supplied the new Waterside Workers' Union, which was formed and registered under the Arbitration Act, with most of its members, and the despatch of the "Athenic" on Nov. 18 with a full cargo of produce was recognized as the turning-point of the struggle. On Dec. 20 the whole strike was declared off except in the mines, and the following month the miners also accepted the inevitable. In the case of all the principal unions the employers had been able to make registration under the Arbitration Act a condition of the settlement. The Government, and especially Mr. Massey, the Premier, and his Minister of Justice, Mr. Heaman, gained great credit for the resolution and the energy with which they faced Labour dictation.

*The War.*—Britain's declaration of war against Germany was read in Wellington from the steps of Parliament House on the afternoon of Aug. 5 1914 by Lord Liverpool.[1] The news was received with enthusiasm, and the country threw itself eagerly into the work of recruiting, equipping, raising war funds and the like. The New Zealand Advance Expeditionary Force (1,419), destined for German Samoa, left Wellington on Aug. 15, and the Main Expeditionary Force (7,761) on Oct. 15. Parliament, which had assembled on June 25, and before the outbreak of war was for the third successive session dealing with the Legislative Council Bill above described, put the measure through, but otherwise there was little controversial legislation. The characteristic work of the session was the passing of 13 war measures. A Banking Amendment Act empowered the Governor in Council to make bank-notes legal tender. By the Regulation of Trade and Commerce Act the same authority was enabled to fix maximum prices of goods, to prohibit exportation, and to suspend or modify the Labour laws. The Mortgages Extension Act[2] prevented a mortgagee from calling in or exercising his power of sale except with the leave of the Court.

The War Regulations Act empowered the Governor in Council to make regulations prohibiting acts "injurious to the public safety, the defence of New Zealand, or the effective conduct of the military or naval operations of His Majesty during the present war." In the discussion of these measures and of the other issues presented by the war the spirit of party was kept creditably in abeyance. There was, however, no strong feeling in the House and little more in the country against proceeding with the general election on its due date at the end of the year. But no election campaign was ever more languidly conducted. With most of the old issues out of the way and the shadow of the war over everything, the dividing line between the principal parties was less distinct than ever, and the fact was emphasized by the gulf that divided both from the socialism of the Labour party. The polling took place on Dec. 10 1914, and the result, as modified by sundry election petitions and the by-elections arising therefrom, was: Government (Reform party) 41; Opposition (Liberals) 32; Labour 7. A position which would leave the Government in a majority of one after the election of the Speaker plainly presented the alternatives of deadlock and dissolution, with the grave weakening and possible paralysis of the country's war effort in either event.

*Trentham Camp.*—When Parliament met on June 24 1915 the fierceness of the party storm which raged round the defence administration, especially in regard to the alleged mismanagement of Trentham Camp, made the outlook very black, but wise leadership on both sides averted disaster. The announcement of the success of the negotiations for coalition on the first anniversary of the declaration of war contributed not a little to the success of the celebrations. The National Government was sworn in on Aug. 12 1915, the members with their principal portfolios being as follows: Mr. W. F. Massey (Reform), Prime Minister, Lands and Labour; Sir Joseph G. Ward (Liberal), Finance and Postmaster-General; Mr. (afterwards Sir) James Allen (Reform), Defence; Mr. W. H. (afterwards Sir William) Herries (Reform), Railways and Native Affairs; Mr. A. L. Herdman (Reform), Attorney-General; Mr. R. McNab (Liberal), Justice and Marine; Mr. (afterwards Sir) William Fraser (Reform), Public Works; Mr. G. W. Russell (Liberal), Internal Affairs and Public Health; Sir Francis H. D. Bell, K.C. (Reform), leader of the Legislative Council; Mr. A. M. Myers (Liberal), Customs, Munitions and Supplies; Mr. W. D. S. Macdonald (Liberal), Agriculture and Mines; Mr. J. A. Hanan (Liberal), Education; Mr. Maui Pomare (Reform), Cook and other islands, member of Executive representing native race. In 1917 Mr. McNab died and Mr. T. M. Wilford (Liberal) became Minister

[1] Lord Islington, who was appointed governor in 1910, was succeeded by Lord Liverpool in 1912. The title was changed to governor-general on June 28 1917. Lord Jellicoe succeeded in 1920.

[2] The operation of this measure, subject to various amendments, has been extended to Dec. 31 1922. Legislation to restrain the increase of rent was not passed till 1916, and remained in force until Dec. 31 1921.

of Justice and Marine; and after Mr. Herdman's resignation on Feb. 4 1918 to take a seat on the Supreme Court bench, Mr. H. D. Guthrie (Reform) joined the Government as Minister of Lands, Sir Francis Bell taking the attorney-generalship. With these changes the National Government remained in office throughout the war, the life of Parliament, which in ordinary course should have expired in Dec. 1917, being extended for two years. The Government was never popular, and during its last year was extremely unpopular. But by enabling the country to concentrate its energies upon the prosecution of the war, and to make the necessary provision for meeting the cost, it accomplished a great work which dwarfed that of every other government in the history of the Dominion and would have been beyond the power of either of the parties standing alone.

Nearly 63,000 voluntary recruits had been accepted for service or registered as medically fit in 21 months of war, and more than 46,000 had been despatched oversea, before it became necessary to think of conscription. The patriotism of the people and the suspension of party government saved the National Cabinet from any serious difficulty in making the change. The Military Service bill was wisely brought in while the voluntary system, though weakening in its appeal, was still giving excellent results. The justice of compulsion commended it to popular sentiment almost as much as its necessity, and the bill, which was introduced by Sir James Allen on May 24 1916, passed its second reading in the House of Representatives by 49 votes to 5, and became law on Aug. 1 1916. Except from some of the Labour members the bill met with no opposition. The men who were selected in the first ballot under the Act taken on Nov. 23 1916 went into camp without trouble or hitch of any kind, and the Act worked for the most part with remarkable smoothness throughout—a result in large measure due to the quiet determination of Sir James Allen, upon whom, both as Minister of Defence throughout, and as acting Prime Minister during the long absences of Mr. Massey and Sir Joseph Ward on War Cabinet and Imperial Conference business, the whole burden fell.

His most serious difficulty was a coal strike in April 1917, which was avowedly inspired by hostility to conscription, despite the fact that miners were being treated by the Military Service boards even more indulgently than the farmers as persons engaged in an essential industry. A settlement which apparently recognized this right to exemption as absolute and condoned an illegal strike was generally considered to have purchased peace at too high a price, but the fear that the trouble would recur was not realized. A few months later the opponents of conscription received encouragement from an unexpected quarter. In July 1917, shortly after their return from the first Imperial War Cabinet meetings, it was suggested by both leaders that it was time to consider how many more men the country could send. But Sir James Allen, who had already called up 10,000 men under the Military Service Act and was then proceeding with his ninth ballot, made it clear a few days later that the suggestion implied no faltering with the compulsory scheme, and a united Cabinet saw it through. Class C of the Second Division of the Expeditionary Force Reserve—married men with two children—had just received their summons when Germany collapsed. The total number of men provided was 124,211, of whom 91,941 were volunteers. A country 10,000 m. from the main theatre of war had, from a population of 1,090,000, sent 100,444 soldiers and nurses across the seas.

*War Finance.*—The first three of Sir Joseph Ward's four war budgets placed the burden of the new taxation in an increasing degree on incomes. That of 1915 effected no drastic increase but established an important change in principle which seems likely to be permanent. The exemption from income-tax which income derived directly from land or mortgages of land had hitherto enjoyed, on the ground that land and mortgages were liable to land-tax on their capital value, was removed. In 1916 a tax of 45% on excess profits arising during the war was tried, but its operation proved to be so inequitable that it was not renewed. In 1917 the land-tax, which before the war had ranged on a graduated scale from 1d. to 7d. in the pound on the unimproved value, with an exemption of £500, was increased 50%, with an additional 50% in the case of absentees. The exemption of incomes not exceeding £300 was retained, but on higher incomes the tax, which before the war began at 6d. for persons and 1s. for companies and rose to 1s. 4d. when the income exceeded £2,400, was made to range from 1s. 3d. for persons and 2s. 3d. for companies to a maximum of 7s. 6d. on incomes exceeding £6,700. Additional revenue was also obtained from increased stamp duties, customs duties, postages, railway fares and freights and in other ways, but these items were small in comparison with the income-tax. The total revenue derived from taxation rose from £5,918,084 in 1913–4 to £13,801,643 in 1918–9, the contributions of land-tax and income-tax being £767,451 and £554,271 respectively in 1913–4, and £1,512,683 and £6,219,336 respectively in 1918–9. The taxation per head was £5 10s. in 1913–4 and £12 7s. 8d. in 1918–9; the estimate for 1920–1 was £15 7s. 6d.

No attempt was made, however, to meet the cost of the war from revenue, and in 1916, with the war expenditure approaching £1,000,000 a month and the London market no longer able to supply all the Dominion's needs, the Government was compelled for the first time to float a large loan locally. The £8,000,000 asked for in Sept. 1916 was over-subscribed to the extent of £1,250,000 within the eleven days allowed, and shortly afterwards the subscriptions totalled £11,000,000. Subsequent loans were less eagerly taken up, but there were no failures. The success was due in part to the provision which from 1917 onwards enforced contributions to these loans from taxpayers whose taxable income exceeded £700. Between March 31 1914 and 1920 the gross debt of the Dominion rose from £99,730,427 to £201,170,755. The net indebtedness per head on the dates named was £84 2s. 8d. and £165 3s. 1d. respectively. Of the gross increase of £101,440,328 no less than £85,157,459 had been raised in the Dominion, £80,089,025 being for war loans. The percentage of the total debt raised in each of the money markets and outstanding on March 31 1910 and 1920 respectively was: 1910—London 77·09, New Zealand 17·42, Australia 5·49; 1920—London 47·58, New Zealand 50·74, Australia 1·68.

*Imperial Government War Supplies.*—New Zealand was well able to bear the drastic increase in taxation and to find the loan moneys needed, owing to the high prices ruling for her produce throughout the war and the terms on which the greater part of it was disposed of.[1] Not merely did the British navy keep the sea-ways open for her trade, but the British Government supplied the tonnage to take her produce away and paid for it almost regardless of the risks of ocean traffic in time of war. Through the agency of the New Zealand Government, all the Dominion's exportable mutton, lamb and beef were purchased by the Imperial Government as from March 3 1915, and contracts for other produce followed, viz. scheelite (Sept. 20 1915); cheese (Nov. 4 1915); wool (Dec. 1 1916); sheepskins (Feb. 5 1917); hides (March 31 1917); freezing companies' slipe wool (March 31 1917); and butter (Nov. 20 1917). The Imperial Government Supplies Department, which the Dominion Government organized for the purchase and control of all this produce, was one of the most efficient of its business enterprises. The prices paid for the wool were fixed at 55% above those ruling in 1913–4; the Imperial Government also undertook to return to the wool-growers half the profits in wool sold for other than military purposes.[2] In other cases the schedules of

[1] The bank returns illustrate the Dominion's war prosperity. The deposits, which were £25,733,187 in 1913, rose subsequently as follows: 1915 £31,433,653; 1916 £37,757,917; 1917 £42,930,713; 1918 £45,562,939; 1919 £50,489,444; 1920 £59,405,341. The ratio of advances to deposits in 1916 was 71·48, the lowest yet recorded. On the other hand, the effect of excessive importing and the lower prices of produce is shown in the withdrawal of £11,775,290 during the Dec. quarter of 1920, and in the excess of advances over deposits during the March quarter of 1921, amounting to £5,290,610. The deposits in the Post Office Savings Bank increased from £17,131,414 in 1913 to £38,393,131 in 1919.

[2] Of some 2,000,000 bales of wool purchased by the Imperial Government only 9,668 were lost in transit, representing less than 0·1% of the war-time purchases. In 1920, when the wool-growers

prices were revised from time to time. In the case of frozen meat advances had been made since June 1918 to the extent of 75% of the value after the meat has been in store six weeks. In the case of butter and cheese 90% of the value was advanced on any remaining in store for fourteen days before shipment. Half of the profits arising from the sale of butter in the United Kingdom was returnable to the producers. The price paid by the Imperial Government for creamery butter, first-grade, was 157s. per cwt. in 1917–8 and 181s. in 1918–20. First-grade cheese was purchased at 7½d. per lb. in 1915–6; 9½d. in 1916–7; 10d. in 1917–8; and 10¾d. in 1918–20. By various extensions most of these purchases were continued till the end of July 1920, but the contract for butter did not lapse till March 31 1921. The total amount paid to the producers of the Dominion by the Imperial Government down to the end of the month which covered the Armistice (Nov. 30 1918) was £74,658,816. By March 31 1921 the total was £156,022,005, the principal items being: wool £60,377,260; frozen meat £53,039,535; cheese £21,158,968; butter £16,283,650.

Through the generosity, regularity and promptitude of these payments the period of the war, which must otherwise have been one of financial stress or even disaster for the Dominion, became " an era of guaranteed prosperity "; and it is unfortunate that the arrangement has closed in circumstances which have tended to blind the producers and the people to the extent of their obligation.

The sudden reverse of fortune which the world-wide depression of 1920–1 brought upon the farmers of the Dominion was aggravated by the congestion of produce held for the Imperial Government in the ports of the Dominion and by the holding of wool, mostly in the United Kingdom, to the value of about £22,000,000, until it became a drug on the market, and the responsible authorities were severely criticized in consequence. But when the trouble has passed the Dominion's indebtedness to the mother country for the absolute security and the unique prosperity which it enjoyed during the war will stand out once more in true perspective.

*War Pensions and Repatriation.*—The first War Pensions Act was passed in 1915. By this and various amending measures the weekly pension in case of death ranges from 30s. for the widow of a private to £3 10s. for the widow of a brigadier-general or major-general, with the addition, if there are any children, of 10s. payable to the widow, regardless of rank, and 10s. for each child. In the case of disablement the maximum weekly pension is £2 for a private, £1 for his wife and 10s. for each child. For a brigadier-general or major-general the maximum is £3 5s. with £1 12s. 6d. for the wife and 10s. for each child. The number of war pensions in force on March 31 1920 was 34,571 (24,661 temporary, 9,910 permanent), of the gross annual value of £1,869,365.[1]

By a series of Discharged Soldiers' Settlement Acts (1915–8) liberal provision was also made for the settlement of discharged soldiers on the land or for financing them in the purchase of houses in the towns. A Repatriation Department was also established early in 1919 " for the purpose of helping every discharged soldier requiring assistance to secure for himself a position in the community at least as good as that relinquished by him when he enlisted for war service." The help rendered has been under three main headings of employment, training, and financial assistance. Under the first head it was found that only about 25% of the discharged soldiers desired help from the Government. By March 20 1921 the Department had in the first twenty-five months of its operations dealt with 50,181 cases. Suitable employment had been found for 22,902 discharged soldiers; vocational training with sustenance or subsidy had been arranged for 5,584 men; the after-care officers had dealt with 1,114 chest cases and 1,040 others. Loans for acquiring or establishing businesses had been granted to 5,516 applicants, and for the purchase of furniture, tools, etc., to 11,370 others, while financial assistance of other kinds had been given in 4,187 cases. The total of these advances was £1,801,883 against which instalments of £475,351 had been collected.

The total expenditure on repatriation to March 31 1921 was as follows:—

| | |
|---|---|
| Discharged Soldiers' Settlement Act: | |
| Advances for stock and purchase of houses and private land . . . . . | £18,130,964 |
| Land Settlements Act: | |
| (*a*) Capital value of 293 estates, comprising 489,915 ac., purchased, subdivided and offered to soldiers | £5,423,253 |
| (*b*) Cost of 15 estates, comprising 40,511 ac., purchased and now being subdivided and prepared for settlement . . . . . | £364,195 |
| Repatriation Act: | |
| Financial assistance for establishment of businesses, for purchase of furniture, tools, etc., and for sustenance, etc. . . . . | £1,801,883 |
| | £25,720,295 |

The number of discharged soldiers thus settled on the land was 7,341; and 1,601 more had taken up leases of Crown land. The total area of their holdings was 2,872,574 acres. In addition 9,200 were helped to purchase or erect town dwellings under provisions which authorize advances up to £1,150 for the purpose, making the total number of discharged soldiers enabled by the Department to acquire land 18,142.

The Repatriation Department has certainly been one of the most efficient and economical of the enterprises enforced by the war. The land settlement policy, on the other hand, has been too generous to be businesslike. The bounty of the State to its defenders has not been limited by the ordinary canons of prudent lending, and advances have sometimes been made up to the full value of the land. The " boom " prices of land, and especially of dairying and grazing land, during the period 1917–21 presented a serious obstacle to the scheme, nor had the utmost caution prevented a department which had had to make large purchases of land from aggravating the evil. The soldier who had bought at the prices then ruling and borrowed most of the purchase-money was faced with the project that he might be sorely tried if hard times continued.

*Cost of Living.*—As in other countries, one of the main charges against the Government was its failure to check the steady rise in the cost of living; yet New Zealand probably suffered as little from this world-wide malady or from the negligence of its Government as any other country. The Government relied chiefly on the Board of Trade, which was appointed in March 1916, under the Cost of Living Act 1915, to deal with the questions covered by the title of the Act and to advise the Government generally on the development and protection of trade, industry and commerce. This Board fixed the prices of wheat, flour, bread, milk, groceries, timber and other articles from time to time; arranged in 1918 (in view of the expected local shortage) for the purchase by the Government of 4,000,000 bus. of wheat in Australia, for the guarantee to the Dominion farmers of a minimum price for their wheat, and subsequently for the purchase of the crop by the Government. It also devised a scheme in 1916 for fixing the price of butter at about 1s. 7d. per lb. throughout the war. The scheme was abandoned in the following year and the price fixed at 1s. 9d. In 1917–8 the half-share of profits (£307,919) from the sale of New Zealand butter in the United Kingdom, which, by arrangement with the Imperial Government, was returnable to the producers, and for the two following seasons a grant of £340,000 from the Consolidated Fund, were applied towards the equalization of prices as between factories

received £1,620,000 for their share of the surplus profits, a large number of them, after the tide of their prosperity had already turned, displayed a due sense of their obligations to those who had made this wonderful result possible. Under a scheme initiated by Mr. E. Newman, M.P., himself a sheep-farmer, £214,209 (less income-tax amounting to £31,340) was set aside for the benefit of seamen of the navy and mercantile marine disabled during the war and the dependents of those who had lost their lives.

[1] On the same date there were 19,993 old-age pensions in force and 3,444 widows' pensions. The expenditure on the former during the year 1919–20 was £732,968, representing a cost of 12s. 6d. per head as against 7s. 7d. in 1913–4. The normal amount of an old-age pension is now £39 per annum. The expenditure on widows' pensions in 1919–20 was £136,815.

which exported and those which supplied the local markets at the prescribed price.[1]

In June 1918 the Board of Trade arranged with the Colonial Sugar Co. for the supply of sugar (No. 1A) from Fiji to the New Zealand market at a price of £21 per ton f.o.b. Auckland till June 30 1917. The price was afterwards increased to £22 10s. and remained at that figure till the end of the war. Even after a later increase had brought the price up to £23 15s. for the nine months ending March 31 1920, it was believed to be the lowest then being paid anywhere.

In its report issued in Sept. 1917 the Board of Trade expressed the opinion that probably 90% of the population had benefited to some extent by the prevalence of war-prices, even after allowing for depreciations in the purchasing power of the sovereign. The extra millions that poured into the Dominion through the appreciation of its produce were, of course, a great boon to the country as a whole, but the rise in retail prices was naturally more clearly perceived. The increase % in the prices of the three principal food groups for the month of July in each of the six years over the prices prevailing in July 1914 is officially estimated as follows: 1915, 12·15; 1916, 19·25; 1917, 26·82; 1918, 39·35; 1919, 43·85; 1920, 67·38. The rapid advance between July 1919 and July 1920, which almost equalled that of the first three years combined, was fully maintained during the following five months, the figure for Dec. 1920 being 78·97, but there was afterwards a slight decline. On Feb. 15 1921 the increase of food prices over the level of July 1914 was 75·05%, as against 149% for the United Kingdom on March 1. During the six months ended Feb. 1921 the cost of living, as measured by the prices of food, rent, fuel and light combined, showed a rise of 59·52% above those of the six months before the war (Jan.–July 1914). There was little economy during these years except what was involuntary. The amount invested by the public on the totalizator at the race meetings rose from £3,538,188 in the racing year 1912–3 to £8,788,788 in 1919–20. The expenditure on alcoholic liquor, which was £4,137,653 in 1913, amounted to £7,587,229 in 1920.

Another of the instruments by which the Government sought to deal with the cost of living was the Court of Arbitration. Established for the purpose of adjudicating upon industrial disputes which the machinery of conciliation had failed to compose, this tribunal had tended more and more to the position of a court of first instance dealing with questions of wages. It was at first suspected by the employers and afterwards hated by a large section of the workers, and in recent disputes it has sometimes been ignored by the Government itself in favour of special tribunals. The war kept the Arbitration Court busy with applications for increased wages, but it did not always pass the whole burden of increased prices on to the employers, and the miners, who stood outside the Arbitration Act, could boast of a 27% increase in wages, while unions which relied on the court had to be content with 10 to 15%. The president (Mr. Justice Stringer) said that "the court raised wages in sympathy with the cost of living and after a year found that the wages were farther off than ever from being in correspondence with the increased cost of living. The court also realized that there must be a limit to the amount paid in wages, especially in a community competing with other countries." Nevertheless an Act passed in Dec. 1918 empowered the court to review current awards and directed it in so doing to take into consideration any increase in the cost of living since its last award. This enactment the court accepted as a mandatory instruction, in the absence of any countervailing consideration, to raise wages in correspondence with the cost of living, and the subsequent applications for bonuses have been determined on figures supplied by the Government statistician. In short, "as has been said, the court now considers that its main function is the maintenance of real wages." Parliament passes on to the Arbitration Court a task which is beyond its power and the court wonders that Parliament, which has the necessary power, does not take on the work itself. In 1920 Parliament withdrew its mandate and gave the court a discretion in the matter, but it has not yet found the cure for profiteering.

*End of Coalition Government, 1919.*—Mr. Massey and Sir Joseph Ward, who had left the Dominion on Dec. 12 1918 in order to represent New Zealand at the Peace Conference, returned on Aug. 6 1919. Parliament had been summoned for the 28th. The question about the coming session, which had excited the keenest interest, was determined a week in advance by the resignation of Sir Joseph Ward, promptly followed by that of all his Liberal colleagues. Formed on Aug. 12 1915, the National Government had come to an end on Aug. 21 1919. The news was received with deep regret by independent men, who feared that the division of the constitutional forces and the general unrest and discontent would give revolutionary labour a unique opportunity. But the enthusiasm of the Liberals, whose fighting men had long been chafing under the restraints of the Coalition, was unmistakable. The fulfilment of the purpose for which the National Government was formed was the reason given by Sir Joseph Ward for his action, but he also complained that he had not been properly consulted.

Mr. Massey's position was one of great difficulty. Within a week of the session and within four months of the general election he had to form a new party Cabinet and, with no assured majority, make a start with the work of reconstruction. But he faced the position boldly, and emerged from the session not only with his new Cabinet unbeaten but with a large number of useful measures to its credit and with his own prestige as a leader much enhanced. Apart from this personal success, the striking features of the 1919 session were, first, Sir James Allen's budget (Sept. 23), which provided for an ordinary expenditure of £22,441,057 and loans totalling £30,325,000, all but £1,000,000 being for the benefit of discharged soldiers and which gave a genuine earnest of economy by reducing departmental expenditure outside the Education Department by £400,000; and, secondly, the unfortunate party competition of which the soldiers' gratuities became the subject. The Government proposal amounted to 1s. 6d. per day, the Liberal leader proposed 2s., and the Labour party 4s. The competition illustrated in a striking way the dangers which a non-party control had averted during the war, but the fear that it would be renewed on the hustings was not realized. The Government's proposal, which involved an expenditure of £6,050,000, was carried, and the question was not reopened.

In the campaign which followed the rising of Parliament on Nov. 5 1919 the dividing line between the Reform party and the Liberals appeared to be more arbitrary than ever. Except that the Liberals advocated a state bank, the nationalization of coal-mines and flour-mills, and proportional representation —subjects in which the electors displayed no great interest— there was little in the generalities of either programme that might not as well have been in the other. Labour, on the other hand, was in the field with a thorough-going programme of nationalization and socialism, and under leadership which inspired more distrust and alarm than the programme itself.

*The Rise of Labour.*—For the first time since it had helped the Liberals to victory at the general election of 1890, Labour had become a really formidable force in New Zealand politics, and it was now both independent and revolutionary. In July 1913 negotiations for reconciling the antagonism between the old trade-union ideals and methods and those of direct action and class warfare had resulted in the prefixing of "United" to the title of the Federation of Labour, with a constitution which left the burning question of registering under the Arbitration Act to the option of each union. But the result was in the main a triumph for the revolutionaries, nor was their power more than temporarily checked by the crushing defeat of their policy in the great strike of 1913. Through varying phases of organization they gained steadily throughout the war at the expense of the moderate elements. A notable development on the industrial

[1] In 1920, when the Imperial Government had offered 2s. 6d. per lb. for the coming season's butter, Parliament voted £600,000 to enable the producers to supply the local market at the retail price of 2s. 3d.

side was the grouping in 1919 of some of the more militant unions in the National Industrial Alliance of Labour, which has superseded the Federation of Labour. A check was administered to the amalgamation of industrial unions in 1918 by an important decision of the full court that only those unions can amalgamate whose members are engaged in the same industry. The direct march towards the ideal of "one big union" is thus barred, but the way left clear for organization on a national basis, and this organization is proceeding. The aim of the National Alliance of Labour, which was approved by a representative conference in 1920, is to have all the industries nationally organized, and to federate these national organizations. The Alliance is to be a "Federation of National Federations." With the federations of the freezing workers, waterside workers, seamen, drivers, tramwaymen, miners and railwaymen linked up, and the number still growing, the Alliance of Labour claims to be already the most powerful Labour organization ever established in the Dominion. It is noteworthy that the Amalgamated Society of Railway Servants, upon whose loyalty the Government was able to rely in the great strike of 1913 and in other troubles, has now thrown in its lot with the direct actionists. Industrially the Labour party thus promises to be better organized for war than ever before, and it is in a warlike mood. The litigious spirit fostered by the machinery of compulsory arbitration, which has made New Zealand singularly barren of such experiments in mutual goodwill and understanding between capital and labour as the Whitley Councils, is now yielding to a more aggressive policy on the part of the workers which will make peaceful coöperation still more difficult.

Politically also the Labour party has made a great advance. The violence of its anti-patriotic and anti-military propaganda was restrained during the war by the stringency of the war regulations against seditious language and language calculated to interfere with recruiting; but war-weariness, the cost of living, and all the shortcomings, real and imaginary, of the National Government gave the party towards the close of the war a great opportunity as the most convenient vehicle for popular discontent. In 1918 three of the revolutionary leaders who had been convicted of offences in relation to the great strike or against the war regulations were successful at by-elections,[1] and two of the seats were captured from the Government. The inertness of a Government which regarded its position as secure was largely responsible for this result, but the success of a party whose attitude to the war had been described by one of its own leaders as that of "dignified neutrality" was a strange paradox in the last year of the war. Its choice of candidates indicated the complete political ascendency of the revolutionary element in the party. At the general election of 1919 the prospects of Labour were improved by the disruption of the Liberal-Reform Coalition, and it had candidates in 50 of the 76 non-Maori constituencies, the contest in 34 cases being triangular.

As one of its leaders said, the Labour party had thus "the chance of its life," but the fact that outsiders could see this as clearly as its own members was probably the turning-point of the election. Hatred of the party's war record, distrust of its leaders, and the fear that it might at least be strong enough to secure the balance of power set large numbers of electors seeking the most effective method of voting against Labour. By their prejudice no less than by their principles the Reform party were more widely separated from Labour than the Liberals, and Mr. Massey's declarations against coöperating with Labour were rather more emphatic than the Liberal leader's. Disapproval of the way in which the Liberals had broken up the Coalition, and admiration of the manner in which Mr. Massey faced the crisis thus forced upon him, must also have helped the swing of the pendulum in the direction of the Government. The polling took place on Dec. 17 1919 and resulted as follows: Government (Reform) 47; Opposition (Liberals) 20; Labour 8; Independent Labour 2; Independent 3. The thoroughness of the Reform party's victory, which excited general surprise, was in part due to the chances of an unscientific electoral system. The second ballot had been tried at the elections of 1908 and 1911, but the collective bargaining for votes which it induced was the main cause of its repeal in 1912. The hope that the Massey Government, which repealed it, would provide some better remedy for the anomalies produced by three-cornered fights in single-member districts was disappointed. The official Opposition estimate of the voting in the European constituencies, after amending it by transferring from the Liberals the votes cast for the three Independent Labour or Liberal-Labour candidates to the Independents, is as follows: Government (Reform), 206,461; Opposition, 182,426; Labour, 127,024; Independent Labour, 14,411; Independents, 12,345. On a proportionate basis the Government would have had approximately 30 seats, the Opposition 26 and Labour 18, instead of 44, 22 and 8 respectively, with 2 to apportion among the Independents. These calculations relate to the European constituencies only. The four Maori electorates gave three supporters to the Government and one to the Opposition. Next to Mr. Massey's personal triumph and the rise of the Labour vote, the defeat of Sir Joseph Ward, the Liberal leader, in a constituency which had stood by him in the 32 years of his political career, was the outstanding feature, and none was more widely regretted.

Between the general election and the meeting of Parliament in June 1920 Labour troubles and the Prince of Wales's visit kept the Government fully occupied. Discontent had been rife in the coal-mines throughout the war, and in April 1917 Sir James Allen had been compelled to settle a threatened strike by concessions for which the need for maintaining the Dominion's military efforts undiminished during the acutest crisis of the war was held to be the only sufficient plea. But the truce did not last long and the rejection by the mineowners of the men's demands led in Aug. 1919 to the adoption of a "go-slow" policy in all the mines. The output, which before the war had averaged some 2,250,000 tons per annum, was reduced by about one-third. The supplies for both household and manufacturing purposes were very short; public services, such as railways, tramways, and gasworks, were embarrassed and curtailed; and a system of rationing was established for the first time. In Feb. 1920 Mr. Massey convened a meeting of the parties and succeeded in effecting a settlement. The principal demand of the men, which was for the replacement of the contract system by one of fixed wages, was rejected, but a minimum payment of 12s. per shift averaged over each fortnightly period was conceded and also a general increase of wages.

Another long-standing trouble was handled in a way that brought the Government less credit. The railway workers, to whom the country was especially indebted for industrious and loyal service during the war, had not been rewarded by the advantages which other sections of labour had obtained by militant tactics. After a long delay their grievances were referred to a commission presided over by Mr. Justice Stringer, which in March 1920 recommended a bonus of 6s. a week, representing an advance of 44% to cover a 42% rise in the cost of living. The railway men, who were able to quote the statement of the Premier himself that the cost of living had increased 62%, described the report as an insult and pressed their demand with redoubled vigour. As the Government still temporized, the Engineers', Firemen, and Cleaners' Association struck and were followed by the Amalgamated Society of Railway Servants. After it had lasted three days (April 29–May 1) the strike was settled on the basis of the immediate resumption of work and the reference of the claims to arbitration, which resulted, as was inevitable, in substantial concessions to the men.

Public opinion censured the Railway Department for the procrastination which had inflamed genuine grievances and the men for spoiling a good case by bad tactics. The sting of the performance was that it was timed for the close of the first week of the Prince of Wales's visit and threatened it with disaster. But the Prince himself treated the incident with his usual tact,

[1] The vacancy in one of these constituencies was caused by the forfeiture of a Labour M.P.'s seat through his absence from Parliament owing to his conviction and imprisonment for disobeying the call to military service.

turned it to profit among the strikers no less than among their critics, and received abundant evidence of their personal loyalty and goodwill. Nor between his arrival in Auckland on April 24 1920 and his departure from Lyttleton on May 22 was there anything else to mar the brilliant success of his visit. Speaking broadly, it may be said that the advance of democracy in New Zealand and the development of her national spirit have merely intensified her loyalty to the Crown as an essential link of Empire. She has, of course, her revolutionaries, who profess that one flag is as good for them as another and no better, but the English doctrinaire who toys with republicanism has no analogue in a Dominion where Radical and Conservative alike can see in the Crown the symbol and guarantee of the Imperial unity upon which "all that we have and are" depends. The Prince of Wales quickened this opinion and sentiment with a personal enthusiasm unparalleled before. None of his compliments was more heartily appreciated than the remark in his speech at the parliamentary luncheon (May 7) that "there is certainly no country more stolidly and unrepentantly British than this Dominion of New Zealand." The stolidity and unrepentance of the Dominion's attitude to its parent stock have been powerfully fortified by the Prince's visit.

During the recess the Government and the country suffered a severe loss in the retirement of Sir James Allen, who resigned in March in order to take the High Commissionership in succession to Sir Thomas Mackenzie, whose tenure of the office since 1912, and especially during the war years, had given great satisfaction. It was nevertheless with a strong team that Mr. Massey was able to face Parliament on June 24. The names and chief portfolios of the reconstructed Ministry were as follows: Mr. W. F. Massey, Prime Minister, Finance and Railways; Sir William H. Herries, Native Affairs and Labour; Sir William Fraser, Mines; Sir Francis H. D. Bell, Attorney-General and leader of Legislative Council; Mr. D. H. Guthrie, Lands and Repatriation; Mr. W. Nosworthy, Agriculture and Immigration; Mr. J. G. Coates, Public Works and Postmaster-General; Mr. E. P. Lee, Justice and External Affairs; Mr. C. J. Parr, Education and Public Health; Mr. C. J. Anderson, Internal Affairs and Mr. Maui Pomare, Cook and other islands and member of Executive representing native race. Sir R. Heaton Rhodes was shortly after appointed Minister of Defence. Without retiring from the Ministry Sir William Herries and Sir William Fraser later resigned their portfolios, which were distributed as follows: Mines to Mr. Massey, Native Affairs to Mr. Coates and Labour to Mr. Anderson. In March 1921 Mr. W. Downie Stewart joined the Government as Minister of Internal Affairs.

The Opposition's official amendment to the address in reply was rejected by 45 votes to 23, the minority including eight Labour members; and the Government were not seriously challenged throughout this session. The death of the newly elected Liberal leader, Mr. W. D. S. Macdonald, on Aug. 31 greatly increased the difficulties of the Opposition. Internal dissensions in an attenuated party have made the task of his successor, Mr. T. M. Wilford, a very embarrassing one.

Mr. Massey's first budget sounded a note of caution, but in providing for a revenue of £27,712,700, and an expenditure of £26,893,497 (the figures for 1919–20 being £26,081,340 and £23,781,924 respectively), and for loans which, including £10,000,000 for renewals, amounted to £24,800,000, it gave no clear indication of the tapering off which it recommended. There was no general increase of taxation, but a more equitable adjustment of its burdens, which recognized for the first time in New Zealand the distinction between earned and unearned income, was effected. Defence is apparently one of the departments in which efficiency is to be sacrificed to economy. The leading features of the new scheme, which is to cost about £600,000 per annum when fully established, are the reduction of the period of Territorial training from seven years to four, the limit now being fixed at the recruit's 22nd year instead of the 25th; the establishment of "recruit" or "general training" period in the 18th to 19th year for both fit and unfit youths; and an increase in the camp training (47 days in all) with greatly reduced half-day and evening parades. The scheme is not yet in operation, and there may be no training camps for two or three years. The session passed without any hint of a naval policy.

Though the expiry of the Imperial Government's contracts for the purchase of the Dominion's produce, and the danger threatened to the coming season by that Government's inability to clear the immense accumulations of meat in the cold storage of all the chief ports of the Dominion or to dispose of the wool accumulated in England, had attracted a good deal of attention during the session, the gravity of the approaching crisis was not generally perceived. The suddenness with which the world-wide depression hit the Dominion towards the end of the year surprised not a few even of those who had prophesied trouble. The sheep-farmers were the most serious sufferers from the collapse of prices which the war had "boomed," but butter and cheese to some extent saved the position. The effect of the depreciation of exports was aggravated by an unprecedented glut of imports. Importers had been ordering freely to meet the shortages of recent years, and as orders had usually been only filled *pro rata* they were often sent sufficiently in excess of requirements to provide for the estimated deduction.

The unexpected filling of these liberal and long-standing orders resulted in immense importations from Britain and the United States and at high prices. The imports, which had averaged about £20,000,000 in the four years before the war, rose from £30,671,439 in 1919 to £61,595,828 in 1920—about £65 a head and £15,153,882 in excess of the exports. Some of the chief items were: Boots and shoes 1919 £442,901, 1920 £1,189,575; woollen goods 1919 £527,468, 1920 £2,412,428; motor vehicles 1919 £1,135,320, 1920 £2,934,239. The returns for the first quarter of 1921 show that the process had been checked, but the balance was still adverse. The merchant and the banker were having their full share of the farmers' anxieties, and unemployment had begun to show its head. A country which profited for so many years from the troubles of the world could not complain if it was compelled to share them for a while.

*External Affairs.*—The impulse which induced the Ward Government in 1909 to offer a dreadnought to the Admiralty, and the country to confirm the offer, has been justly described as a spasm rather than a policy, and it cannot be said that the Dominion has even yet evolved a policy in these matters. The military defence of the country was put on a reasonable basis by the establishment of compulsory training in 1909–10, but naval policy made no comparable advance. The £20,000 which New Zealand agreed to pay towards the maintenance of a British Squadron in Australasian waters was increased to £40,000 in 1903 and to £100,000 in 1908. At the Imperial Defence Conference of 1909 arrangements were made for the establishment of a Pacific fleet, with the Dominion's gift ship as the flagship of its China unit, and 7 vessels of this unit, manned and officered as far as possible by New Zealanders, were to be stationed in peace-time in New Zealand waters. The concentration of the Empire's naval strength in European waters, which was dictated by the growing pressure of the German competition, upset this arrangement, and in 1912 the Mackenzie Government, with the entire approval of the people, assented to the transfer of New Zealand's battle-cruiser to the North Sea. Sir James Allen, who became Minister of Defence in the same year, was a strong advocate of a policy of naval self-reliance, and in 1913 a Naval Defence Act was passed which provided for the establishment of a New Zealand naval force which in time of war was to be at the disposal of the British Government. The scheme was opposed by Sir Joseph Ward on the ground that what the Empire needed was a single undivided navy and that New Zealand did not want and could not afford a navy of her own, and the division on the measure followed party lines. It is certain that public sentiment would have condemned the scheme if it had not provided for the automatic transfer of the force to the Admiralty in the event of war.

In 1919 Lord Jellicoe, who visited New Zealand in that year (Aug. 23–Oct. 2) on his naval mission, and whom the Dominion was proud to welcome back in 1920 (Sept. 27) as its governor-

general, proposed that Britain and Australasia should join in forming a Far Eastern fleet; that New Zealand should contribute, man and control a unit to be called the "New Zealand Division of the Royal Navy"; and that the whole fleet should pass into the control of the Admiralty in time of war. The fact that each party welcomed this solution as a finding in its favour was a sufficient proof of its wisdom, but pending joint Imperial action on the subject the country marked time. Meanwhile it discontinued the naval subsidy and expected to pay £260,000 for the upkeep of its only vessels, the light cruiser "Chatham" and the training-ship "Philomel," during the year 1920–1.

There was not the slightest drift towards separation from the Empire or even towards the quasi-independence which desires a foreign policy of its own under the same Crown. The admission of the Dominions to the League of Nations excited no elation in New Zealand, and the revolution which it was supposed to have worked in their constitutional relations to the United Kingdom was generally regarded as a step in the wrong direction. Mr. Massey's statement in the House that, if he thought the League of Nations would weaken the Imperial connexion in any way, he would prefer to see the Dominion out of it, squared exactly with public sentiment. New Zealand considered that one foreign policy was enough for the Empire, and, while hoping that some kind of representative control might be ultimately evolved, it would much prefer the control of the British Foreign Office, informed by the fullest consultation practicable, to any division of authority.

Incidentally the difference of attitude which the issue of the Pacific Mandates revealed, supplied the Dominion with another argument against federation with Australia. The New Zealand Government was advised by its law officers from the first that it should receive its mandate for Western Samoa from the Imperial Government, and the advice was in accordance with the sentiment of the country. The more assertive nationalism of Australia claimed the right to deal direct with the League of Nations. As there was nothing to suggest that this divergence of ideals and tendencies was decreasing or likely to decrease, John Ballance's declaration in 1891 that "the whole weight of the argument is against New Zealand entering into any federation except a federation with the Mother Country," seemed in 1921 still to be nearer the mark than the prophecy in 1912 of Mr. Andrew Fisher, then Prime Minister of Australia, that "New Zealand will probably be in the Federation within twenty years." But the problem of putting the Imperial partnership upon a business footing by a federal scheme or otherwise received no close and consecutive attention. Neither the project of an Empire Parliament, which Sir Joseph Ward submitted to the Imperial Conference of 1911, nor Mr. Massey's advocacy of an Imperial Executive in the New Zealand Parliament in 1921 (March 16), was the outcome of careful thought, public discussion or popular demand; nor did either of these proposals contribute anything to the education of public opinion.

**NICARAGUA** (*see* 19.642*).—The estimated pop. in 1913 was 689,891† by Dec. 31 1917 it had risen to 746,000. In 1920 about 75% of the people lived in the western half of the country, where the inhabitants are predominantly white or native Indian. In the E. are large numbers of Sambos, Caribbean negroes and Indians, and some Americans. Communication between the two coasts is difficult; passenger traffic usually goes by way of Costa Rica, and freight by way of the Panama Canal.

*Social and Economic Conditions.*—There were in 1920 356 elementary schools, ten secondary schools, and the three universities at Managua, León and Granada. Educational activity had been great since 1917. Until recently all public instruction was in the hands of the religious orders, and in 1920 two normal schools were still directed by the Church. The Jesuit school in Granada was built with state funds and received Government aid. The secondary schools were subsidized by the State, and instruction in the universities was free. Special scholarships were established, by means of which students are sent to the United States for training in teaching and horticulture.

Agriculture has increased in recent years, but is retarded by labour shortage. In the E. bananas are the chief crop; coco-nuts and rice are also grown. Wheat grows in Nueva Segovia and tobacco in Masaya. In the W. coffee is the chief crop, sugar, cacao, corn, and beans also being raised. Tropical products excepted, most of the food for eastern Nicaragua comes from the United States. From the W. a little surplus food is exported. There are about 1,200,000 cattle. The coffee crop is usually about 22,500,000 pounds. In 1921 the coffee crisis was acute; the 1918–9 crop had sold well, and some advances were made on the 1919–20 crop in expectation of prices as high as $.30, but as the market fell those who had obtained advances of $.14 were fortunate. High duties in France limited the market to the United States. The 1920–1 crop was large, trading was light, the price being one-third the cost of production. The chief forest products are mahogany and cedar, with some production of dye woods and medicinal plants. American and British interests are engaged in gold and silver mining. Copper and precious stones are also obtained. The only railway on the W. side is the Pacific line, 171 m. long, from Corinto to León, Managua, Granada and Diriamba, with short branches. There are a few private lines in the east. A New Orleans syndicate obtained a concession for 10 years, beginning in 1918, to build from Bluefields to Lahone Grande. Americans hold 51% of the stock in this enterprise and have escrow control of 49%, which secures a loan of $1,060,000. In the spring of 1921 a loan was made of $9,000,000 for constructing the Atlantic railway, repurchase of the Pacific railway and payment of the 1909 bonds. Work began on a line from Chinandega to Playa Grande and the Honduran frontier, which is to be part of the International Railways on the Honduras and Salvador boundaries.

Imports and exports in pounds sterling for five years were as follows:—

| | 1914 | 1915 | 1916 | 1917 | 1918 |
|---|---|---|---|---|---|
| Imports . . | 826,865 | 631,843 | 955,519 | 1,278,613 | 1,185,961 |
| Exports . . | 991,010 | 913,440 | 1,056,972 | 1,195,051 | 1,550,988 |

Customs receipts, 1918, were £199,629; 1919, £294,961. Imports in 1918 of cotton goods were worth $1,580,037; iron and steel, $709,990; wheat flour, $356,705. Exports consisted of coffee, timber, bananas, hides and sugar. Trade with the United States amounted to $4,630,457 in imports and $6,412,921 in exports. The remainder of the trade was distributed among England, France, Chile, Panama, Mexico and Canada.

The revenues and expenditures for four years in pounds sterling were:—

| | 1915–6 | 1916–7 | 1917–8 | 1918–9 |
|---|---|---|---|---|
| Revenues . . . . . | 418,019 | 460,479 | 480,321 | 598,547 |
| Expenditures . . . . . | 357,883 | 396,159 | 351,553 | 424,167 |

The debt on Oct. 20 1917 was $21,390,521; it had been reduced by Jan. 1919, through amortizations and negotiations, to $10,238,589. In Jan. 1920 it was $9,884,023. The internal debt in Sept. 1916 was 10,000,000 cordobas (nominally equivalent to U.S. dollars and fluctuating very little). In 1917 the bonded debts were reëstablished, deferred interest was provided for, the floating debt settled, and the annual budget limited. Surplus revenues which have been over $600,000 have been applied equally to the foreign debt, the floating debt and public improvements.

*History.*—José Madriz, elected president in 1909, failed to win recognition from the United States. He seemed for a time to be about to defeat his enemies in the field, but his unsuccessful expedition against Bluefields, during which the U.S. marines intervened to protect American property, resulted in the success of the revolutionists. Madriz left Managua on Aug. 20 1910, the forces under Juan M. Estrada entering it next day. Estrada, though of the artisan class, was backed by the conservative families of Granada as well as by some liberals. His Government was soon recognized by the United States, relations being resumed in January. The public treasury was immediately emptied to pay revolutionary debts. By the autumn of 1911 some 25,000,000 pesos of depreciated paper currency had been circulated, much

** These figures indicate the volume and page number of the previous article.*

of it going to members of the party in power. These pesos were later retired on a basis of $.08 each. This ruinous finance, added to the prostration begun by internal war, was disastrous to agriculture, commerce and transportation. The conservative Government, aided by the U.S. Department of State, effected on Nov. 5 1910 an agreement providing for Estrada's continuance in the presidency, for a commission containing Americans to adjust revolutionary claims and those arising from cancellation of concessions granted by Zelaya (*see* 19.645), and for a treaty with the United States providing for a loan. Estrada was elected Dec. 31 for a term of two years, and was promptly recognized by President Taft. But troubles with Emiliano Chamorro's faction over the constitution, and with Gen. Mena's faction over control of the army, resulted in Estrada's resignation. The United States intervened, and with the consent of Gen. Mena, who was for some months in actual control, Adolfo Diáz succeeded to the presidency. The plan for financial rehabilitation, arranged for by treaty on June 6 1911, was checked by failure of the treaty in the U.S. Senate. However, a private loan was effected and the currency reformed by the adoption, on Nov. 12 1912, of a monetary unit, the cordoba having the value of the U.S. dollar. The loan was secured by the customs duties, and control of the national railways was obtained by an American corporation. In 1912 the customs collectorship was entrusted to Col. C. D. Ham, formerly of the customs service in the Philippine Is., who served the interests of Nicaragua, the U.S. State Department, and the holders of the national debt. The interest rate on the debt was reduced, and much of the debt itself paid. A Claims Commission, sitting from May 1 1911 until late in 1914, awarded $1,840,432 out of the $13,808,161 demanded; U.S. claims of $7,576,564 were scaled to $538,749. In Oct. 1911 Gen. Mena induced the Assembly to elect him president for the term beginning Jan. 1 1913, whereupon Diáz removed him from the Ministry of War, and he fled, his place being given to Emiliano Chamorro. Mena's faction, really the old Zelaya party, led by Gen. Zeledón in the illness of Mena, was opposed by the United States in the interests of the banking firms which had undertaken the reform of Nicaraguan finances. At the instance of Diáz, U.S. marines kept open the lines of communications, protected American lives and property, and sustained the Government. On Nov. 2 1912 Diáz was reëlected for the term 1913–7, and was maintained in power by American marines. He ruled under the Constitution of March 1 1912, as amended in Articles 168 and 170 on April 5 1913. In the latter year an additional loan of $1,000,000 was obtained in New York, but during the World War it became necessary to issue unsecured paper currency. This caused depreciation, which was checked in 1915. In Feb. 1913 a treaty was signed whereby Nicaragua gave to the United States, for $3,000,000, exclusive canal rights, with accessory control over the entrances on the Corn Is. and in the Gulf of Fonseca. An effort to extend the treaty to limit Nicaraguan foreign relations failed, but a treaty providing for a loan was finally ratified, and proclaimed on June 24 1916. Protests by Costa Rica and Salvador against alleged infringements of their sovereignty by this treaty were heard before the Central American Court of Justice, which sustained the complaints. Its decision has been ignored by both parties to the treaty, in practical derogation of the Washington Conventions of 1907, which were intended to safeguard the interests of all Central American countries and to promote the settlement of difficulties through arbitration. The policy of the United States caused resentment in many parts of Central America, where guarantees of American investments are considered evidence of imperial designs. Police control, even though maintaining a minority in power, has improved public and private finance, and given peace to the country. In 1919 Nicaragua became involved in the troubles of Honduras by allowing troops to gather on her border to invade her neighbour; after warning from the United States, Nicaragua desisted from the enterprise. She broke relations with Germany on April 18 1917, and declared war on May 8. She was represented at Versailles as an original member of the League of Nations, and ratified the Treaty on April 5 1920, but up to the middle of Dec. had not deposited her ratification in Paris. Nicaragua did not enter the Central American Union organized in 1921.

In Oct. 1916 Emiliano Chamorro, the candidate committed to the American financial programme, was elected as president, and inaugurated Jan. 1 1917 for the term ending Dec. 31 1920. On Jan. 1 1921 Diego Manuel Chamorro, retiring minister to the United States, was inaugurated as president. (H. I. P.)

**NICHOLAS II.** (1868–1918), Tsar of Russia (*see* 19.655). In view of the tragic end of the Tsar Nicholas II. and his family, in the Russian revolution, it may be noted that, even in the lifetime of his father, Alexander III., his mind had been deeply imbued by mystic belief in divine rights and providential guidance, and he was prepared to suffer and to endure, if necessary, in carrying out the duties of his office. His intellectual preparation as heir to the throne was decidedly insufficient, especially considering the position he would ultimately hold. He was left in the background for some time and even later no special efforts, such as would naturally be expected, were made to prepare him for his future extraordinary task by any elaborate and well-considered teaching. An English tutor, Mr. Heath, taught him indeed good English, and inspired a love of sports and healthy exercise, while a Russian general, Danilovitch, supervised his military training, but there was no attempt to provide him with the comprehensive knowledge required from one whom fate had destined to rule an immense empire. The only occasion which was offered to the young Tsarevitch to acquaint himself with the problems of the world was his journey to the Far East, so abruptly cut short in Kioto by the sabre cut of a Japanese fanatic. It is not to be wondered at that Nicholas II.'s range of ideas was not very wide or profound, although he was by no means unintelligent and possessed in high degree the royal habit to move with ease and tact in complicated personal surroundings. His disposition towards fatalistic mysticism made him particularly amenable to the promptings of superstitious and irrational suggestion. He told Stolypin on one occasion, when he had to take an important decision, that he was loth to do so, because he was sure that his interference would be accompanied by bad luck; he saw a warning in the fact that he had been born on May 6, the day when the Church honoured the memory of Job; he was predestinated to say with Job: "As soon as I apprehend a danger, it occurs, and all the misfortunes dreaded by me come over me." His career was bent with many dismal predestinations of every kind. He wedded Princess Alix of Hesse, at the deathbed of his father; at the festival of his Coronation more than three thousand people were crushed to death through the negligence of the officials who had to arrange a distribution of bounties; and during the Coronation itself the imperial chain on his breast fell to the ground. Such impressions contributed strongly to inspire him with a mystic resignation, especially unsuitable for a monarch who had to lead the nation through times of great crisis at home and in foreign affairs.

Nicholas II.'s political outlook was dominated by a kind of theocratic or hieratic spirit; he was looking back for inspirations to the ideas and customs of the Moscovite period; he was induced to impersonate the figure of Alexis Mikhailovitch, the father of the western reformer Peter the Great; in 1913 the tercentenary of Michail Feodorovitch's accession to the throne after the "Great Troubles" was celebrated with great splendour and emphasis. Pilgrimages were performed with great devotion and circumstance.

The courtiers and bureaucrats in the immediate surroundings of the Tsar, men like Sipiaguin, Nicolas Maklakov, and Sabler, took advantage of these prepossessions in order to keep up a constant hostility against progressive reformers and western adaptations. But the most dangerous representative of mystic reaction was the Tsar's consort, the Empress Alexandra Feodorovna. Of German descent on her father's side and of English descent on the side of her mother (Princess Alice, the daughter of Queen Victoria), she had received her education in England, but, on coming to Russia, she surrendered completely to the most extreme form of theocratic exaltation. While her sister, the widow of the Grand Duke Sergius, killed by a ter-

rorist, had devoted herself to an almost monastic life at the head of a community of hospital nurses, Alexandra Feodorovna, highly strung and hysterical, sought providential guidance in the midst of unbalanced women and false prophets like the French medium Philippe and the famous Rasputin. The latter obtained a hold on her through the hypnotizing influence he exercised over her son, the Tsarevitch Alexis, a boy affected by the rare disease of hereditary haemophilia. But the crafty peasant had contrived to obtain gradually a psychical domination over the Empress and her friends which made it possible for him to distribute political favours and to have his say in the most important affairs of State. The Empress considered him as the God-sent representative of the Russian nation, of that mass of peasants which, as she was convinced, was the firm mainstay of autocracy in Russia. And in the later years of Nicholas II.'s reign, the years of great trial and danger, Alexandra Feodorovna stepped in more and more often to direct the Tsar's choice of his ministers and to prevent him from making concessions to the spirit of the time.

The suspicion that Alexandra Feodorovna was secretly favouring the cause of Germany and revealing military secrets to the Kaiser—a suspicion often expressed abroad and popularly accepted in Russia—is, according to most competent witnesses, devoid of any basis in fact. The Empress was intensely patriotic in her own way, opposed to the aggressive policy of the Hohenzollerns, and never advocated a treacherous compromise with the Central Powers. A former lady-in-waiting, Princess Vassiltchikov, who towards the close of 1916 brought the project of such a compromise from Germany was promptly ordered out of Petrograd. Nevertheless, Alexandra Feodorovna proved to be the evil genius of the Russian dynasty, by her blind and obstinate support of reactionary tendencies and of worthless adventurers, at a time when a wise and firm policy of reform was more needed than ever. All the better representatives of the dynasty—the Dowager Empress Maria Feodorovna, the Grand Duke Nicholas Mikhailovitch, the Grand Duchess Victoria, warned the Empress Alexandra Feodorovna of the imminent danger of that regime of fleeting ministerial shadows which set in after the catastrophe of the War Office in 1915.

The Emperor remained passive as commander-in-chief at headquarters while the Empress Alexandra spurned all advice with contempt and continued to pull the strings by dismissing men like Sazonov and Palivanov, and appointing timeservers like Sturmer, Protopopov, or Galitzin. The assassination of Rasputin did not frighten but enraged her; she erected a kind of shrine over the body of the prophet and sent the Grand Duke Dmitry Pavlovitch, who had taken part in the murder, into exile. Her power was broken only by the revolution.

The thread of the Romanov dynasty was cut without much resistance. When in March 1917 the Emperor received at headquarters a telegram from the president of the Duma informing him of the events of Petrograd and demanding his abdication, and MM. Gutchkov and Shulgin arrived with the act of abdication itself, he submitted with fatalistic composure. He refused to give up his crown to his son with Grand Duke Michael as regent, because he did not wish to trust the boy to the danger of a political storm; and his abdication was made in favour of the Grand Duke Michael, who in his turn refused to accept the crown unless it was tendered to him by the will of the people. The last chance of a regime of constitutional monarchy was cut short. Proposals were made on behalf of the British Government to allow Nicholas II. and his family to take up their abode in England; but the Provisional Government in Petrograd did not accede to that plan. Kerensky and Milyukov declared that the imperial family were in safety in Russia. Later on the Emperor submitted meekly to be transferred from Pskov to Tsarskoe Selo and then to Tobolsk, where he was interned with his family—his wife, his son and his four daughters for months.

The life in Tobolsk has been described by a French tutor, M. Gilliard, who followed the imperial family into exile. All the qualities of the unfortunate prisoners of State came to the fore in these sad times. The Tsar taught his son history and Russian literature, the family circle assembled in the evening to read and converse, they prayed and attended the church services with touching devotion. In Ekaterinburg, where they were transferred by the Bolsheviks in 1918, their captivity assumed an oppressive form. They were huddled together in an apartment consisting of two bedrooms and one sitting-room. Their guard consisted mainly of Lettish soldiers, while Russians were kept on the outskirts of the house; they had to listen to the uproar and the ribald songs of their watchmen; the walls of the sitting-room were covered with obscene drawings and inscriptions; the head gaoler, Yourkovsky, was a fanatical communist, a Jew, who harboured feelings of fierce hatred against the potentates of Holy Russia.

The end came in connexion with Kolchak's advance on the Ural in 1918. The Soviet of Commissaries in Moscow enjoined the greatest vigilance to the Ekaterinburg commissar, Yourkovsky, and the commander of the guard, Medvediev, without indicating any means for removing the prisoners from the threatened zone. The communists of Ekaterinburg held a secret meeting in which they decided to put the Tsar and his family to death, and sent an order in this sense to Yourkovsky. The latter demanded that it should be duly signed, and 16 signatures were affixed to it. On the night of July 16 Yourkovsky roused the prisoners and conducted them into a cellar of the house. Medvediev, with the Lettish guards, entered the room while some Russian soldiers were looking in from the staircase. Yourkovsky placed the seven doomed persons at one end of the room and read the sentence hurriedly by torchlight. The Tsar stepped forward and said something indistinctly, when Yourkovsky drew his revolver and shot him in the head. A general fusillade followed, and not content with this, the executioners pierced the bodies with their bayonets and struck them with the butt-end of their rifles. The Grand Duchess Tatiana is said to have recovered consciousness for a while, but she was struck down once more and for ever. Besides the seven members of the imperial family four of their attendants were probably slaughtered the same night. In the course of the next few days the corpses were removed to an isolated spot in the neighbourhood of Ekaterinburg and destroyed by fire, after having been soaked with petroleum. A few objects of apparel were later picked up on the spot. (P. Vi.)

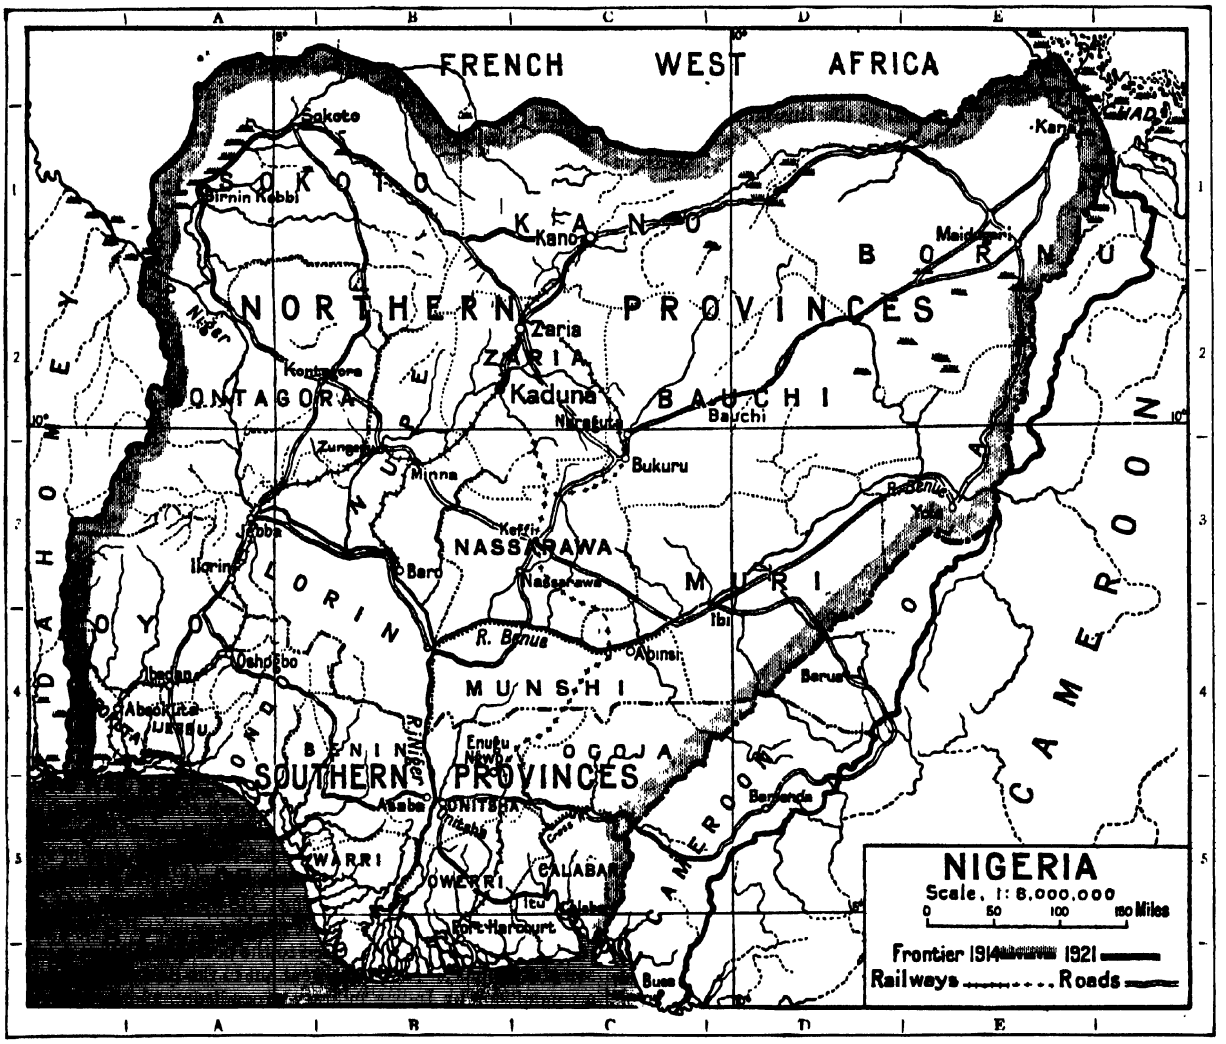
**NICHOLAS** (1841–1921), King of Montenegro, was the last member of the House of Petrovich Njegosh to reign over a separate Montenegrin realm, his dominions being now merged in the kingdom of the Serbs, Croats and Slovenes. The story of the last twenty years of his life is very largely the contemporary history of Montenegro (*see* MONTENEGRO). His grant of a constitution in 1907 was followed by a period of violent internal conflict between him and his opponents, whose position had been strengthened by the elections to the Skupshtina, whom he sought to discredit by the Cetinje bomb plot mystification. His assumption of the kingly title in 1910 marked a further stage in the evolution of his plans, of which it constituted a public notification, and aroused hostile comment among his own people as well as in Serbia. The Balkan wars resulted in a marked *diminutio capitis* for Nicholas, who failed to play a conspicuous part in them and was forced to call in Serbian aid before Scutari. At this time already the survival of a Montenegrin throne appeared a doubtful problem. In the World War the breach between him and his people was complete, and even before the final act the old monarch was apostrophized derisively as Nicholas the first and Petrovich the last. He died at Antibes March 1 1921, and was buried at San Remo.

**NICHOLAS** (NIKOLAI NIKOLAYEVICH), (1856– ), Russian Grand Duke, grandson of the Tsar Nicholas I. and first cousin of the Tsar Alexander III., was born Nov. 6 1856. As a junior officer he passed through the General Staff College. During the war with Turkey in 1877–8 he was on the General Staff, and won the Cross of St. George for his courage and energy during the crossing of the Danube near Zimnitza. His further military service was passed in the Guard Hussar regiment of which he

became commander in 1884. He then commanded a brigade and, in 1900, the 2nd Guard Cavalry Division. His brilliant capacities assured his rapid advancement. At the manœuvres of 1890 he already commanded four cavalry divisions, and in 1895 he became Inspector-General of the Russian cavalry. He held this post for ten years, a period which is regarded as a bright epoch in the history of the Russian cavalry. With a firm hand he carried through the reform of the cavalry schools, the cavalry reserve, the cavalry remount service, and improved the method of instruction and direction of the cavalry units. In 1902 he was selected to command the Russian forces in case of a war with Germany. On the creation of the Council of National Defence in 1905, the Grand Duke was appointed its President, and the same year he received the command of the Guards and of the St. Petersburg Military District. In 1908 he left the Council of National Defence.

At the outbreak of the World War the Grand Duke was nominated to the Supreme Command of the Russian armies. Thus suddenly called on to assume the highest responsibility, the Grand Duke undertook it under particularly difficult conditions. He had to work with people with whom he had never worked before, and who were almost unknown to him. Since 1909 he had not taken part in the preparatory defence of the country; the principal work, after mobilization, the deployment of the armies, had been done without him, without his ideas. In fulfilling a plan not formed by himself he was at first overcome by the force of events. But in the later development of operations after the first battles his personal will and generalship were able to assert themselves, notably in the transfer of operations to the left bank of the Vistula in Oct. 1914. In the campaign of 1915, hampered as he was by the want of material resources, he was unable to maintain the front of the Narew–Vistula–San-Carpathians against the formidable effort of the Germans and Austrians, but, heavy as were the losses of the Russian army, he managed to withdraw it without anywhere incurring a Sedan, to a line which, substantially, it maintained throughout 1916 and 1917. In August 1915, the Tsar having assumed personal command on the main front, the Grand Duke was sent to the Caucasus as governor-general and commander-in-chief. Here, with Yudenich's assistance, he carried out the successful offensive campaigns of Erzerum and Trebizond, and his work contributed greatly to relieve the situation of the Allies in the East. After the Revolution he retired to his villa in the Crimea, where he remained until its occupation by the Bolshevik forces in 1918.

**NICHOLSON, EDWARD WILLIAM BYRON** (1849–1912), English scholar and librarian, was born at St. Helier March 16 1849. Educated at Tonbridge and Trinity College, Oxford, in 1873 he became librarian of the London Institution, and in 1877 founded the international conference of librarians and the Library Association. In 1882 he succeeded H. O. Coxe as Bodley's librarian. He published commentaries on the *Gospel according to the Hebrews* (1879) and *St. Matthew* (1881), *Keltic Researches* (1904), papers on philology, etc., and wrote the article "Mandeville" in the *E.B.* He died at Oxford March 7 1912.



**NICHOLSON, MEREDITH** (1866– ), American writer, was born at Crawfordsville, Ind., Dec. 9 1866. He was educated in the public schools of Indianapolis, and for many years he was engaged in journalism in that city. His works include: *The Hoosiers* (1900); *The Main Chance* (1903); *Zelda Damaron* (1904); *The House of a Thousand Candles* (1905); *The Port of Missing Men* (1907); *A Hoosier Chronicle* (1912); *The Provincial American* (1912); *Otherwise Phyllis* (1913); *The Madness of May* (1917); *The Valley of Democracy* (1918); *Lady Larkspur* (1919); *Blacksheep! Blacksheep!* (1920); and *The Man in the Street* (1921).

**NICHOLSON, WILLIAM** (1872– ), English painter and engraver, was born at Newark Feb. 5 1872, and was educated at the Magnus school, Newark. He studied at the Académie Julien, Paris, and about 1894 began experimenting in wood engraving, producing some admirable work in that medium, characterized by the use of bold masses of black and white or of sombre greys and browns, relieved by touches of bright colour. In this manner he illustrated *An Alphabet* (1898); *An Almanac of Twelve Sports* (with Rudyard Kipling; 1898); *London Types* (with W. E. Henley; 1898); *Characters of Romance* (1900); *A Square Book of Animals* (with A. Waugh; 1900), and engraved some well-known portraits, including that of Queen Victoria. He also collaborated with James Pryde under the name of "The Beggarstaff Brothers" in designing some remarkable posters. To the set of lithographs entitled "Britain's Aims and Ideals," published during the World War, he contributed "The End of War." As a painter he is best known for his interiors and still-life pictures, such as "The Hundred Jugs" (1916), "Souvenirs de Babette," "Miss Simpson's Boots" and "The Striped Shawl"; but his work also includes landscapes—for example "The Hill above Harlech"—generally in a low key, and many portraits, including those of W. E. Henley, the painter's mother, Sir W. C. Pakenham (for the Imperial War Museum); Ursula Lutyens, and "The Girl with the Tattered Glove." He is represented in the Luxembourg, Paris; the Tate Gallery; the Walker Art Gallery, Liverpool; the Glasgow Gallery; and the Fitzwilliam Museum, Cambridge.

**NICHOLSON, WILLIAM GUSTAVUS NICHOLSON, 1ST BARON** (1845–1918), British field-marshal, was born March 2 1845, and joined the Royal Engineers in 1865. He served in the Afghan War, 1878–80, for which he was given a brevet majority, and he took part in the Egyptian campaign of 1882. For service on the staff in Burma in 1885–6 he was promoted brevet lieutenant-colonel, and he reached the rank of colonel in 1891. He next served as chief of the staff in the Tirah campaign, for which he received the K.C.B., and as adjutant-general in India. In 1899 he went out to South Africa as military secretary to Lord Roberts, but on arrival he was placed at the head of the transport service and was promoted major-general. He was appointed Director of Mobilization and Intelligence at the War Office in 1901 and was shortly afterwards promoted lieutenant-general; this position he held till early in 1904 when he went to the Far East as chief military attaché with the Japanese forces. At the end of 1905 he was appointed quartermaster-general; in 1906 he was promoted general and in 1908 was transferred to the post of Chief of the Imperial General Staff, which he held during the important period of the Haldane reforms. He was promoted field-marshal in 1911 and, on vacating his appointment at the War Office in the following year, was raised to the peerage as Baron Nicholson of Roundhay. In 1913 he went out to the East as chairman of a commission on Indian military expenditure, and in 1916–7 he was a member of the Dardanelles commission; this was his last public service. He died on Sept. 18 1918. Lord Nicholson was a man of high intellectual attainments and, although somewhat given to controversy, a successful military administrator.

**NIGERIA** (*see* 19.677), the largest British possession in W. Africa, has an area of some 335,700 sq. m. and a population of approximately 17,000,000. The crown Colony of Nigeria, which was formerly known first as Lagos and later as the Colony of Southern Nigeria, has an area of 1,400 sq. m., the rest of the territory being the amalgamated Protectorates of Northern and Southern Nigeria which, with effect from Jan. 1 1914, were brought under a single administration. The task of effecting this amalgamation was entrusted to Sir Frederick Lugard, who in 1912 was transferred from Hong-Kong for the purpose, and assumed charge of both Southern and Northern Nigeria, succeeding Sir Walter Egerton as governor of the former and Sir H. Hesketh Bell as governor of the latter. He bore, as personal to himself, the title of governor-general. Under the scheme of amalgamation, the Colony retained its status, but the authority of its Legislative Council was confined to the small area enclosed within the colonial boundaries, and a post of Administrator was created, the occupant of which was entrusted with the control of the Colony and its affairs under the direction of the governor-general. Mr. F. S. James was appointed to this office, but on his transfer in June 1916 to the post of Colonial Secretary, Straits Settlements, the appointment was not again filled, the duties attaching to it being thereafter discharged by the officer for the time being acting as lieutenant-governor of the Southern Provinces.

The Protectorate of Nigeria was divided into two groups of provinces, each group being placed under the immediate charge

of a lieutenant-governor. The provinces forming each group are as follows: Northern—Bauchi, Bornu, Ilorin, Kano, Kontagora, Munshi, Muri, Nassarawa, Nupe, Sokoto, Yola and Zaria; Southern—Abeokuta, Benin, Calabar, Ijebbu, Ogoja, Ondo, Onitsha, Owerri, Oyo, Warri and Cameroon. The last named of these provinces (*see* CAMEROON) comprises the southern portion of the mandated ex-German territory, the more northern districts of which are incorporated, for administrative purposes, with the provinces of Yola and Bornu respectively, of which they form natural and political parts. The accounts of all the mandated area are kept separately from those of the rest of Nigeria, but an annual grant-in-aid from the Government of Nigeria (£67,000 in 1921) is required in order to square its budget. Each lieutenant-governor is provided with a secretariat, and under the original scheme separate departments were maintained in each group of provinces wherever this was possible. A later development has led to the establishment of single government departments for the whole of Nigeria, the Education and Science Departments, and the police forces of the Northern and Southern Provinces respectively, alone remaining separate. Each lieutenant-governor is directly responsible to the governor for the administration of the group of provinces under his charge; and each province is administered by a Resident who, in his turn, is directly responsible to the lieutenant-governor under whom he serves. Under the original scheme, a small central secretariat was created to assist the governor in dealing with the various departments—*e.g.* the Treasury, the Railway, etc.—which were common to the whole of Nigeria; but the system whereby three wholly unconnected secretariats dealt independently with questions requiring the consideration of the governor was not found to work well, and as from Jan. 1 1921, a Nigerian secretariat was established through which all work submitted to the governor now passes. This office is presided over by a Chief Secretary to Government, who acts for the governor when the latter is absent on leave; and in this department all work of a political character is dealt with by a Secretary for Native Affairs. Mr. C. L. Temple was appointed lieutenant-governor of the Northern Provinces on Jan. 1 1914. He was succeeded in 1917 by Mr. H. S. Goldsmith, who, on his retirement in June 1921, was succeeded by Mr. W. F. Gowers. Mr. (afterwards Sir) Alexander Boyle was lieutenant-governor of the Southern Provinces from Jan. 1 1914, until his retirement in 1920, when he was succeeded by Lt.-Col. Moorhouse. Sir Frederick Lugard held the post of governor-general from Jan. 1914 until his retirement in June 1919, when he was succeeded by Sir Hugh Clifford, the governor of the Gold Coast, as governor of Nigeria. Mr. D. C. Cameron, who has held the post of Central Secretary since the inauguration of the amalgamation, was appointed Chief Secretary to Government on Jan. 1 1921, with precedence over both the lieutenant-governors.

*Administration.*—The system of administration in force in the Northern Provinces is one of indirect rule, the Native Administrations in the Mahommedan emirates, which were in existence at the time of the conquest, having been maintained intact. Each emirate, however, has been divided up for administration purposes into a number of districts, each of which is under the immediate charge of a district head, who is responsible to the emir. Justice is administered by the Mahommedan courts, an *Alkali*, as he is locally called,

being the chief magistrate in each emirate. The operations of the Native Administrations are supervised by the British political officers, who also exercise revisory powers over the decisions of the Mahommedan courts. Capital cases are tried by the emir with the assistance of his Judicial Council, and death-sentences are submitted to the governor and to his Executive Council for confirmation or revision. Every effort is made to support, strengthen and purify the Native Administrations, which continue to be the *de facto* governments of the Mahommedan areas; and even in the pagan districts the more primitive tribal organizations are put, as far as circumstances permit, to a similar use. An annual tax based upon the income of the tax-payer, which has the authority of Mahommedan law, is in force throughout the Northern Provinces. The work of assessment and collection is carried out by the Native Administrations under the close personal supervision of the political officers. Half the proceeds furnish the funds for the Native Administrations, many of which have large balances to their credit. The remainder is paid into the public Treasury, which annually derives from this source revenue of about half a million sterling.

The system of indirect rule through the Native Administrations has been extended with a fair measure of success to the Yoruba States which occupy the western portion of the Southern Provinces, and here a system of direct taxation, similar to that in force in the Northern Provinces, has been introduced since the amalgamation was effected in 1914. Owing to the primitive character of the tribal organizations existing in the remainder of the Southern Provinces, however, action on these lines has not there been found possible, and the administration of the country has accordingly to be conducted more directly by the political officers.

*History.*—The outbreak of war, following so closely upon the amalgamation of the Northern with the Southern Provinces, retarded the completion of the scheme, and for a period paralyzed the activities of the Government of Nigeria. The Nigeria Regiment, which consists of four battalions, a battery, and two companies of mounted infantry, took part successively in the Cameroon and E. African campaigns, in both of which it greatly distinguished itself; and at the time of the signing of the Armistice, a brigade was in readiness for immediate service in Palestine. Officers belonging to the civil department were seconded in large numbers for military service; the local financial position during the first two years of the war occasioned acute anxiety; and the impossibility of obtaining material of all descriptions caused progressive deterioration in the railway and in other similar departments. During 1915 all enemy subjects in Nigeria were deported to Great Britain for internment or repatriation, and their properties in Nigeria, after their businesses had been wound up by an official receiver, were sold by auction in London toward the end of the following year.

In 1914 the treaty with the Egba United Government, which had its seat at Abeokuta, was abrogated with the consent of the *Alake*, and the country, which it had administered and which had hitherto enjoyed a *quasi* independence, was placed upon the same footing as the adjoining Yoruba States. In 1917 a serious rising occurred in Egbaland, in the course of which much property was destroyed and some miles of track on the western railway were torn up by the insurgents. The insurrection was suppressed by the Nigeria Regiment without difficulty; and with this sole exception the peace of Nigeria remained unbroken throughout the whole of the World War. The Mahommedan emirs, the Alafin of Oyo and all the principal chiefs throughout Nigeria evinced from first to last the most unswerving loyalty, and notable contributions to the funds of the Red Cross were made.

*Communications.*—The railway system of Nigeria consists of the western line running from Iddo island in the neighbourhood of Lagos, to Kano, a distance of 705 m. and passing through the important towns of Abeokuta, Ibadan, Oshogbo, Ilorin, Kaduna and Zaria. From Minna, the point at which the junction between the railways of Northern and Southern Nigeria was originally effected, a branch line 111 m. in length runs to Baro on the Niger, which river is spanned at Jebba by a fine railway and road bridge which was completed and opened to traffic in 1917. From Zaria a branch line of 2 ft. 6 in. gauge runs 144 m. to Bukuru on the Bauchi plateau, which is the centre of the tinfield. The railway from Port Harcourt to Enugu Ngwo, a distance of 151 m., was however completed in 1916, thus tapping the colliery at the latter place, which was thereafter able to supply all the fuel required for the whole railway system and for the river and other marine services of the country. The output in 1921 exceeded 800 tons *per diem;* and the cost of production until late in 1919 was approximately 8s. per ton at the pit's mouth, but it had increased by 50% in 1921. This eastern railway was in 1921 being extended to the Benue river, the principal affluent of the Niger, which it will cross at a point a few miles above Abinsi. The railway bridge which is to be here constructed will be the third largest cantilever bridge in the Empire. From the Benue the line will traverse the Nassarawa and Bauchi provinces to a point some 40 m. E. by S. of Bukuru, to which place a branch line is to be constructed, the main line effecting a junction with the western system at Kaduna, the administrative capital of the Northern Provinces. With the exception of the Bauchi Light Railway from Zaria to Bukuru, the gauge throughout the system is 3 ft. 6 in.

A fine system of motor roads links up the Southern Provinces, and it is now possible to motor from Lagos through the Abeokuta, Oyo, Ondo and Benin provinces to the Niger at Asaba, and from Onitsha, on the left bank of the river, through the Onitsha, Owerri and Calabar provinces to the Cross river at Itu. In the Northern Provinces, Ilorin can be reached by motors from Ibadan, and dry-season roads permit their use from Naraguta, on the Zaria-Bukuru railway, through the Bauchi and Bornu provinces to the shores of Lake Chad; from Maidugari, the capital of Burnu, to Kano; from Kano throughout the province of that name; from Zaria to Sokoto, and thence through Birnin Kebbi and Kontagora to Zungeru on the western railway. The road from Zaria to Sokoto is being permanently constructed; and a good motor road has recently been built from Zaria to Kaduna.

River services are maintained by means of shallow-draft stern-wheeler steamboats on the Niger as far as Baro, and during the wet season on the Benue as far as Yola, by the Government and by the Niger Company. Messrs. John Holt & Co. also run steamboats on these rivers.

*Trade.*—During the last two years of the war, during 1919 and until the autumn of 1920, a great boom in local trade was experienced in Nigeria, the prices offering for produce of all descriptions attaining to unprecedentedly high figures. This was followed by a "slump" of great severity which temporarily paralyzed the commerce of the country and reacted strongly upon the public revenue. The following table shows the revenue and expenditure and the principal trade statistics for the years 1913 to 1919 inclusive:—

| | Revenue | Expenditure | Value of Imports | Value of Exports | Total Value of Trade |
|---|---|---|---|---|---|
| | £ | £ | £ | £ | £ |
| 1913 | 3,362,507 | 2,916,801 | 6,331,751 | 7,197,646 | 13,529,397 |
| 1914 | 3,048,381 | 3,596,764 | 6,276,957 | 6,420,461 | 12,697,418 |
| 1915 | 2,703,257 | 3,434,215 | 4,983,728 | 4,946,228 | 9,929,956 |
| 1916 | 2,943,184 | 3,609,638 | 5,174,474 | 6,029,546 | 11,204,020 |
| 1917 | 3,492,738 | 3,219,957 | 5,808,592 | 8,602,486 | 14,411,078 |
| 1918 | 4,014,190 | 3,459,774 | 7,423,158 | 9,511,971 | 16,935,129 |
| 1919 | 4,959,428 | 4,529,176 | 10,798,671 | 14,675,789 | 25,474,460 |

Figures for 1920 were not yet available in July 1921, but the revenue for that year exceeded £6,800,000, and the value of imports and exports beat all previous records.

As from Feb. 1 1919, the importation of "trade" spirits into all the W.A. Colonies and Protectorates was prohibited, causing to Nigeria an annual loss of revenue amounting to about 1½ millions sterling. Partially to compensate for this, export duties on produce, which had been originally imposed as a temporary war measure, were retained after the Armistice and were substantially increased during 1920. During that year approximately three quarters of a million sterling was derived from this source.

The value of the principal imports in 1913 was: cotton goods £1,529,361; spirits £452,939; tobacco, cigars, cigarettes £230,962; cutlery, hardware, etc. £154,857; fish £134,998; grain and flour £125,192; kola nuts £117,324. The first half of 1914 showed a great expansion of trade, which, however, was checked by the outbreak of war; and the value of the imports for the years 1915, 1916 and 1917 fell far below the pre-war level, the largest falling off being in the value and quantity of spirits imported. A recovery was made in 1918, in which year the value of the imports exceeded that for 1913 by more than a million sterling. In 1919, notwithstanding the fact that the importation of "trade" spirits was prohibited as from Feb. 1 of that year, the value of the principal imports was as follows: cotton goods £3,262,933; spirits £99,739; tobacco, etc. £631,531; cutlery, hardware, etc. £293,670; fish £17,300; grain and flour £130,693; and kola nuts £236,848. New items of importance among the imports of this year were coopers' stores (£917,896); bags and sacks (£580,338); salt (£510,839); iron, steel, etc. (£405,791); machinery (£166,680); and kerosene (£159,917).

The values of the principal exports for 1913 were: palm kernels £3,109,818; palm oil £1,854,384; tin £568,428; hides and skins £197,214; ground nuts £174,716; cotton lint £159,223; cocoa £157,480; and timber £106,050. The corresponding figures for 1919 were: palm kernels £4,947,995; palm oil £4,245,893; tin £1,324,074; hides and skins £1,262,140; ground nuts £698,702; cotton lint £484,745; cocoa £1,067,675; and timber £116,820. These increases are in part due to the inflated prices ruling in the produce markets of the world, but the quantity of palm kernels exported had risen from 175,000 tons in 1913 to 216,913 in 1919; of palm oil from 83,000 to 100,913 tons; ground nuts from 19,000 to 39,334 tons; and cocoa from some 5,000 to 25,711 tons.

BIBLIOGRAPHY.—The best list of books and reports relating to Nigeria will be found in Prof. A. B. Keith's *Historical Geography of the British Colonies* (vol. iii., *West Africa*). See also Capt. C. W. J. Orr, *The Making of Northern Nigeria* (1911); C. Martin, *Les Possessions Britanniques en Afrique Occidentale* (1917); *Nigeria Handbook* (1917); Sir F. Lugard, *Report on the Amalgamation of Nigeria* (1919); *Red Book of West Africa* (1920); *Reports in the Blue Book of Nigeria* (1914–20). The annual addresses of the governors of Nigeria contain much that is of interest. (H. CL.)

**NILSSON, CHRISTINE** (1843–1921), Swedish singer (*see* 19.701), died at Copenhagen, Denmark, Nov. 22 1921.

**NITROGEN FIXATION** (*see* 19.714).—Important progress was made after 1910 in the commercial fixation of nitrogen for industrial use. The economic importance of nitrogen fixation is to be found in the possibility of preparing fertilizers from the air, in place of being dependent on the nitrate deposits of Chile, or on ammonia obtained by the carbonization of coal. In addition to the artificial production of agricultural fertilizers, the synthetic manufacture of nitric acid becomes of the utmost importance in time of war, by virtue of the part played by this body in almost every explosive. It is certain that the Central Empires, in the World War, could not have continued fighting, by reason of their economic isolation from normal sources of nitric acid, but for the gigantic nitrogen-fixation factories which were erected at Oppau and elsewhere.

Nitrogen, in its ordinary form, combines directly with the following elements:—lithium, calcium, strontium, barium, magnesium, boron, aluminium, various rare earths, titanium, zirconium, cerium, thorium, silicon, vanadium, niobium, tantalum, chromium, uranium, manganese. In each case a nitride is formed, from which ammonia may be produced by the action of steam, but the commercial fixation of nitrogen as a nitride is, for technical and economic reasons, only possible in one or two instances, namely in the case of aluminium, and possibly also of silicon. Aluminium nitride is manufactured on a considerable scale in France by the Société Générale des Nitrures, by means of the Serpek process (Brit. Pat. 13086/1910). Finely ground alumina (bauxite) is preheated by means of flue gases and, after being mixed with powdered coal, is allowed to pass slowly along an inclined tube containing an electrically heated portion, by means of which the temperature of the charge is raised to about 1800° C. Producer gas, passed through the inclined tube in counter-current to the bauxite, forms the source of nitrogen, and reaction takes place according to the equation: $Al_2O_3+3C+N_2 = 2\,AlN+3CO$. The aluminium nitride is usually subsequently decomposed by means of caustic soda, with production of ammonia and of alumina.

From a commercial aspect, four processes of nitrogen fixation, namely the synthesis of ammonia, the arc process for the manufacture of oxides of nitrogen, the formation of calcium cyanamide (nitrolim) by the interaction of calcium carbide and nitrogen, and the synthesis of alkaline cyanides by the Bucher process, are all of special interest.

*Ammonia Process.*—The technical synthesis of ammonia, in particular, constitutes one of the great landmarks in chemical technology. The method employed consists in circulating a highly compressed mixture of hydrogen and nitrogen through a heated chamber containing a catalyst, by the action of which a small percentage of ammonia is formed according to the equation $3H_2+N_2 = 2NH_3$. This ammonia is subsequently removed from the uncombined gas, either by treatment with water at room temperature or by a process of refrigeration. The gaseous residue, after removal of the ammonia, is circulated once more through the heated catalyst chamber, fresh nitrogen and hydrogen being added to compensate for that transformed into ammonia and to maintain the pressure. In order to economize energy an elaborate system of heat exchangers is provided, by means of which the hot gases leaving the synthesizing bomb are used to heat the incoming gas. The formation of ammonia from its elements is accompanied by a considerable evolution of heat, and the production may, under favourable conditions, become autothermic when once started; that is to say, the heat of reaction may, in the presence of efficient heat exchangers, suffice to maintain the temperature required without the necessity for the supply of extraneous heat. The heat of formation of ammonia increases somewhat with the temperature. Haber, Tamaru and Oeholm (*Zeitschr. für Elektrochem.*, 1915, *21*. 191, 206) give, as the molecular heat of formation at constant pressure, 10,950 calories at 0° C., 12,670 cal. at 466° C., 12,900 cal. at 554° C., and 13,150 cal. at 659° C. By means of this process of circulation alternately through the catalyst chamber and through an ammonia absorption apparatus, the gas mixture treated becomes transformed into ammonia.

The percentage of ammonia formed each time the compressed gas passes the catalyst chamber depends partly on the speed of circulation, that is to say on the time of contact of the gas with the catalyst, and partly on the conditions of equilibrium between nitrogen, hydrogen and ammonia at the temperature and pressure employed, a subject which has been investigated in detail by Haber and his pupils. This equilibrium may be represented by an equation of the usual type,

$$K_p = \frac{P_{NH_3}}{P_{H_2}^{\frac{3}{2}} \times P_{N_2}^{\frac{1}{2}}}$$

obtained by applying the law of mass action to the formation of a gramme molecule of ammonia by the process: $\frac{3}{2}H_2 + \frac{1}{2}N_2 \rightleftarrows NH_3$.

The value of $K_p$, from which the equilibrium ammonia percentage for any required pressure may readily be calculated from the relation given above, varies with the temperature according to the thermodynamically derived equation:—

$$\log_{10}K_p = \frac{2098}{T} - 2{\cdot}5088\log_{10}T - 0{\cdot}0001006T + 0{\cdot}186\times10^{-6}T^2 + 2{\cdot}1.$$

For an approximate calculation of $K_p$, the abbreviated form: $\log_{10}K_p = \frac{2888}{T} - 6{\cdot}134$ may be used.

The equilibrium ammonia content of a gas mixture, containing nitrogen and hydrogen in the ratio of 1 : 3 by volume, is given in the following table:—

| Temperature ° C. | Equilibrium Percentage of Ammonia | | | |
|---|---|---|---|---|
| | At 1 atm. | 30 atm. | 100 atm. | 200 atm. |
| 200 | 15·3 | 67·6 | 80·6 | 85·8 |
| 300 | 2·18 | 31·8 | 52·1 | 62·8 |
| 400 | 0·44 | 10·7 | 25·1 | 36·3 |
| 500 | 0·129 | 3·62 | 10·4 | 17·6 |
| 600 | 0·049 | 1·43 | 4·47 | 8·25 |
| 700 | 0·0223 | 0·66 | 2·14 | 4·11 |
| 800 | 0·0117 | 0·35 | 1·15 | 2·24 |
| 900 | 0·0069 | 0·21 | 0·68 | 1·34 |
| 1000 | 0·0044 | 0·13 | 0·44 | 0·87 |

From the above figures it will be seen that the equilibrium ammonia percentage decreases rapidly with increase in temperature, but is capable of being raised by working under an increased pressure. The most usual working pressures are from 100 to 200 atmospheres, but an attempt has recently been made by Claude to operate the process at pressures greatly in excess of this.

Of the catalysts employed, osmium, uranium, and iron are of special importance, the interest of the first two being mainly historical, in that the first successful synthesis of ammonia by Haber and his pupils was carried out with their aid. In the case of iron the activity of the catalyst is usually increased by incorporating secondary constituents termed "promoters."

While the formation of ammonia begins at as low a temperature as 360° C., the velocity of the reaction is exceedingly slow under such conditions, in spite of the advantageous effect of a relatively low temperature on the equilibrium ammonia percentage, and a working temperature of 500° or over is usual commercially.

The output of a plant having a catalyst chamber of a given size is obviously governed by the percentage of ammonia formed during the passage of the compressed gas through the catalyst, and by the speed of circulation. It is found advantageous in practice to employ a relatively high speed of circulation, rather than to circulate slowly and to obtain a high ammonia percentage in the gas issuing from the catalyst chamber. The quantity of ammonia produced is measured by the space-time-yield (abbreviated S.T.Y.), this being the number of kilogrammes per hour per litre of catalyst space. For purposes of comparison, it is conventional to express the speed of circulation of the gas in litres per hour, at room temperature and pressure, per litre of catalyst space (space-velocity, abbreviated S.V.).

The efficiency of certain catalysts, under the conditions stated, is exemplified by the figures (*see* p. 1137) for osmium (Haber and Le Rossignol, *Zeitschr. für Elektrochem.*, 1913, *19*. 69), uranium (Haber and Greenwood, *ibid.* 1915, *21*. 241), and iron (Maxted, *Ammonia and the Nitrides*, p. 34).

As already stated, the formation of ammonia in the synthesizing chamber is followed by the elimination of ammonia from the circulating gases either by refrigeration, in which case pure anhydrous ammonia is obtained, or by absorption in water. For use as an agricultural fertilizer, the ammonia has to be converted into a suitable salt, usually the sulphate or chloride. In order to avoid the use of sulphuric acid for neutralization, it has been proposed to allow the ammonia to enter into reaction with calcium sulphate in the presence

| Catalyst | Temperature °C. | Pressure in atmospheres | S.V. of gas $10^3\times$ | Percentage of ammonia formed | S.T.Y. |

of carbon dioxide, whereby ammonium sulphate is produced, calcium carbonate being precipitated. For the production of the chloride, several modifications of the well-known Solvay ammonia-soda process have been suggested, by means of which ammonium chloride is formed from common salt, ammonia and carbon dioxide.

The direct synthesis of ammonia constitutes probably the most economical method of fixing nitrogen at present known. The cost of production is regulated principally by that of the hydrogen, the cost of compression being relatively low. On the other hand, the technical difficulties are probably more severe than in any other known industrial chemical operation. The high pressure, combined with a temperature sufficient to render steel of ordinary composition rapidly weakened by the hydrogen contained in the gas employed, has made necessary the construction of furnaces of special design. Further, all raw materials must be of a high degree of purity, by reason of the readiness with which the reaction is impeded and stopped by the presence of traces of catalyst poisons such as sulphur, arsenic, phosphorus, etc. Nitrogen also combines directly with hydrogen at the temperature of the electric arc and, further, under the influence of the silent electric discharge, but these methods have not up to the present given yields sufficient to justify their commercial application.

Immediately previous to and during the World War extensive factories were erected in Germany, at Oppau and Merseburg, for synthesizing ammonia, the tons of nitrogen fixed in this way being reported to have increased from 4,000 in 1913 to 100,000 in 1917. In Great Britain, Synthetic Ammonia & Nitrates, Ltd., was registered by Messrs. Brunner, Mond & Co., Ltd., in 1920 with a capital of £5,000,000. In the United States, the synthesis of ammonia has been taken up on a large scale by the General Chemical Co., and plants exist at Sheffield, Alabama.

*Cyanamide Process.*—A second highly important method of fixing nitrogen consists in forming calcium cyanamide (nitrolim), by the interaction of nitrogen with calcium carbide, $CaC_2+N_2=Ca:NCN+C$. Absorption of nitrogen takes place readily at 1,000° to 1,100° C., with carbide of commercial quality. By the addition of catalysts such as calcium fluoride or calcium chloride, the combination may be carried out at 800° C. The reaction is exothermic, and the temperature of the charge rises considerably owing to the heat produced. Temperatures exceeding 1,400° C. have a marked inhibitive effect on the yield, by reason of the reversible nature of the reaction.

Two types of plant are employed in practice. In those at Odda in Norway, the charge of carbide is reduced to fine powder by grinding and placed in cylindrical firebrick furnaces, which are heated internally to the required temperature by means of carbon resistance rods, nitrogen being admitted under slight pressure. A period of about 36 hours is required for the completion of the reaction, at the end of which time the product contains upwards of 20% of nitrogen. The charge shrinks away from the walls and forms a solid block, which is easily removed. It is the practice at certain other works, particularly those in Germany and Italy, to employ externally heated horizontal retorts. With these, the temperature of reaction is stated to be less easily controlled and trouble is experienced from the adhesion of cyanamide to the walls. Calcium cyanamide, in a finely ground condition, may be used directly as an agricultural fertilizer, ammonia being produced in the soil by hydrolysis: $CaN\cdot CN+3H_2O=2NH_3+CaCO_3$.

The above hydrolysis is also effected by the action of superheated steam, as an industrial operation for the manufacture of ammonia. The fixation of nitrogen by the cyanamide process is of considerable extent and importance. Factories exist at Odda (Norway), Piano d'Orta (Italy), Niagara, Wittenberg, Chorzow, Piesterlch and other places. It is stated that the total world production of cyanamide in 1916 amounted to nearly 1,000,000 tons, while Germany alone, owing to war-time extensions, is reported to have manufactured 886,000 tons in 1917.

*Bucher Process.*—The synthesis of sodium cyanide by the interaction of sodium carbonate, carbon and nitrogen in the presence of iron as a catalyst, according to the equation $Na_2CO_3+4C+N_2=2NaCN+3CO$, constitutes a promising method of nitrogen fixation, the commercial development of which is still in its infancy. The catalytic effect of iron in promoting this formation of cyanides at relatively low temperatures (800–1,000° C.) was noted by Thompson in 1839. Bucher (*Jour. Indust. and Eng. Chem.*, 1917, *9*, 233) drew renewed attention to the process, which has recently been developed industrially in the United States by the Nitrogen Products Co. According to the procedure adopted at Saltville, Virginia (*Jour. Indust. and Eng. Chem.*, 1919, *11*. 1010), coke is ground to a fineness of 200 mesh, and after the admixture of a small quantity of iron the required quantity of soda ash is added. The charge is moistened slightly, kneaded, and extruded in the form of briquettes, which are dried by the action of flue gases. The briquettes are placed in vertical iron or nichrome retorts, which are heated externally in firebrick furnaces to a temperature of 900 to 1,000° C., a current of nitrogen being led through the retorts. The briquettes, after treatment, contain about 20% to 30% of cyanide, which, in the plant in question, is removed in a somewhat novel manner by subsequent extraction with liquid ammonia, in which sodium cyanide is readily soluble. During this extraction process, the main structure of the briquette remains undestroyed, and the uncombined residue may be used for further treatment with nitrogen. The chief technical difficulty lies in the rapid deterioration of the iron retorts at the temperature employed for fixation, the life of these being about 7 to 12 days. Nichrome retorts last longer, but are more expensive to replace. It has been proposed to use an electrically heated type of furnace in which the charge itself forms the resistance. Further, pure nitrogen, although conducive to a high yield of cyanide, is not essential for commercial success. Ferguson and Manning (*Jour. Indust. and Eng. Chem.*, 1919, *11*. 946), in reviewing the replacement of nitrogen by producer gas containing carbon monoxide, state that at 1,000° C. the presence of 15% of carbon monoxide in the nitrogen reduces the yield of cyanide by about 30%, while, if the producer gas contains 60% of carbon monoxide, the yield is one-half of the value obtained with pure nitrogen. This inhibitive effect of carbon monoxide, the reason for which lies in the reversibility of the equation $Na_2CO_3+4C+N_2 \rightleftarrows 2NaCN+3CO$, is even more pronounced at lower temperatures.

Numerous attempts have been made to synthesize barium cyanide industrially from barium oxide or carbonate, carbon and nitrogen. Margueritte and Sourdeval in 1860 (Brit. Pat. 1,027/1860) appear to have been the first to suggest the process which was subsequently improved by Mond (Brit. Pat. 433/1882) and by Readman (Brit. Pat. 6,621/1894). The optimum temperature is about 1,400° C., reaction taking place according to the equation: $BaO+3C+N_2=Ba(CN)_2+CO$. The above synthesis of barium cyanide was at one time worked on a considerable scale, but was not successful commercially, by reason of the deteriorating action of the fused cyanide on the walls of the furnace. It may be noted that the cyanides may readily be hydrolyzed to ammonia by means of superheated steam in an analogous manner to calcium cyanamide. G. W. Heise and H. E. Foote (*Jour. Indust. and Eng. Chem.*, 1920, *12*. 331) state that on treating briquettes containing synthetic sodium cyanide with steam at a pressure of 300 to 330 lb., a yield of ammonia amounting to over 90% of that theoretically possible was obtained in 30 to 45 minutes.

*Arc Process.*—The final method to be considered consists of the synthesis of nitric acid, either by the action of a high-tension electric arc on air or by the explosion of compressed mixtures of air and a combustible gas in the cylinder of an internal combustion engine (Häusser's process). The production of oxides of nitrogen by either method depends on the reaction of nitrogen with oxygen at a high temperature, according to the reversible equation: $N_2+O_2 \rightleftarrows 2NO$. The equilibrium percentage of nitric oxide formed by heating air to various temperatures has been measured by Nernst, Jellinek and Finckh (*Göttinger Nachr.* 1904, p. 261), *Zeitschr. f. anorg. Chem.*, 1905, *45*. 116; 1906, *49*. 212, 229; *Zeitschr. f. Elektrochem.*, 1906, *12*. 527), the results being summarized in the following table:—

| Temperature °C. | Equilibrium Percentage of NO by volume (from air) |
|---|---|
| 1,538 | 0·37 |
| 1,604 | 0·42 |
| 1,760 | 0·64 |
| 1,922 | 0·97 |
| 2,307 | 2·05 |
| 2,402 | 2.23 |
| 2,927 | 5·00 |

Nitric oxide is formed, and consequently also decomposed, at a very high velocity, less than one-thousandth of a second being required for the attainment of equilibrium even at 2,000°, so that, in order to preserve the products formed at arc temperature, these must be removed as quickly as possible from the arc flame; otherwise a less advantageous percentage, corresponding to a temperature lower than the maximum, is obtained. In practice, this rapid cooling is effected by employing a rapid flow of air, which is injected into a specially spread-out arc. Even with these precautions, however,

the concentration of nitric oxide preserved in the issuing gases does not usually exceed two parts per cent by volume, nitric oxide being capable of existence in an undecomposed but metastable condition at temperatures below 1,000°, by reason of the extreme slowness with which decomposition then proceeds.

Of the commercial plants employed, that due to Birkeland and Eyde has been described in 19.714. In the Schönherr type, the arc is struck between an internal electrode placed at the base of a tall vertical metal tube, which forms the second electrode, air being injected with a whirling motion vertically through the furnace. The arc is thus blown out into a flame, the length of which may be as much as 7 yards. The yield of nitric acid is stated to be about 75 grammes per kilowatt hour of energy used. The concentration of the nitric oxide in the issuing gases is 2–2·5%. A further type of "blown arc" furnace, due to Pauling, employs special lighting knives for promoting the formation of the arc.

The exit gases from any of the above types of furnace are cooled to about 50°, and passed into a so-called oxidation chamber, in which the excess of oxygen combines with the nitric oxide, forming nitrogen peroxide, $2NO+O_2=2NO_2$. The nitrogen peroxide is subsequently absorbed by means of water in large granite absorption towers, nitric acid being produced. The process is operated principally in Norway at Notodden and Christiansand.

In the Häusser process, the requisite high temperature is obtained by the explosion of compressed air with a fuel gas in the cylinder of an engine. Enrichment of the air with oxygen is stated (Greenwood, *Industrial Gases*, p. 107) to increase the yield of nitric acid. Thus, air containing 26% of oxygen gave a yield of 10 lb. of nitric acid per 1,000 cub. ft. of combustible gas, compared with a yield of 6·4 lb. with normal air. (E. B. M.)

**NITTI, FRANCESCO SAVERIO** (1868– ), Italian statesman, was born at Melfi (Potenza) in 1868. He had already become known as a barrister and as professor of financial science at the university of Naples, when he first entered Parliament in 1904. He made his reputation as an authority on economic and financial questions, and was Minister of Agriculture, Industry and Trade in the Giolitti Cabinet of 1911–4. When the United States entered the World War in 1917 he was entrusted with an economic mission to that country, and certain of his utterances and acts in this connexion were severely criticized. He became Minister of the Treasury in the Orlando Cabinet from Oct. 1917 to Jan. 1919. On the fall of Orlando he succeeded him as premier, but his administration was a weak one, the Socialists and Communists being allowed to commit innumerable acts of criminal violence with absolute immunity. He was closely associated with the post-war policy of *svalutamento*. The exasperation of the majority of the country at his policy, and the indignation aroused by his treatment of the Dalmatians in Rome, as well as his failure to secure a settlement of the Adriatic problem, led to his fall in June 1920, thus leaving the way open for the return of Giolitti. On his retirement from office he returned to journalism and business.

**NIVELLE, ROBERT GEORGES** (1856– ), French general, was born at Tulle (Correze) on Oct. 15 1856. He became a student at the École Polytechnique on Nov. 1 1876 (after having been entered at St. Cyr) and in 1878, as a sub-lieutenant, went through the course at the school of artillery and engineering. He was made a lieutenant in the 19th Regt. of artillery in Oct. 1880 and was promoted captain on Dec. 29 1887. He became major (*chef d'escadrons*) in July 1901 and served on the China Expeditionary Corps staff during 1900–1. In 1908, while serving at Ozan, he was made a lieutenant-colonel, and three years later, while serving as chief of staff with the Algiers Div., was promoted colonel. In Dec. 1913 he assumed command of the 5th Regt. of artillery at Besançon and was so employed at the outbreak of the World War in Aug. 1914. At the head of this unit he took part in the operations of the 7th Corps in Alsace (including the battle of Dornach) and was specially mentioned in army orders. On Sept. 6 1914 on the 7th Corps front he again distinguished himself. The German pressure had compelled a French withdrawal and it seemed as if the 7th Corps would have to cross the Ourcq. Col. Nivelle, however, swiftly reorganized his artillery and massed it at a vulnerable point. By the intensity of his fire he checked the German advance and enabled the French to recover the ground they had lost. Two weeks later, on the Aisne, he again saved a French withdrawal by skilful disposition of the artillery under his command. On Oct. 27 1914 he was promoted general of brigade. He commanded successively the 44th and 60th Inf. Bdes. on the Aisne, and in Jan. 1915 was responsible for the check of the enemy before Soissons. On Feb. 19 following he took over the command of the 61st Div.; becoming on Dec. 23 a substantive general of division and commander of the III. Army Corps. He went to Verdun at the end of March 1916 and a month later took over the II. Army. He planned the operations (executed by Gen. Mangin) which resulted in the reconquest in four and a half hours of the country S. of the line Thiaumont–Douaumont–Vaux–Damloup, country which the Germans had taken six months to capture and in the taking of which they had sacrificed some of their best troops. On Dec. 12 1916 he was made commander-in-chief of the armies of the N. and N.E.

The choice was inspired by a variety of motives, amongst which the most important were the objections, political and military, raised against more obvious candidates (such as Castelnau, Foch and Pétain), and the feeling that a younger man might solve the problem of break-through which had defeated Joffre. Nivelle was put in command to break traditions and to win the war in the one great effort of which France, after all her losses, was still capable. He was the embodiment of the wave of optimism which swept over the Allied Governments, armies and peoples in the spring of 1917. The story of his failure to realize these expectations need only be summarized here. Accepted by Mr. Lloyd George's Government as commander-in-chief not only of the French but also of the British front, he asserted his authority from the first moment in such a way as to antagonize Sir Douglas Haig's headquarters. When this difficulty had been officially smoothed over, he allowed himself to be taken aback by the sudden withdrawal of the German centre in March 1917, which disconcerted nearly all the preparations for the Franco-British offensive. Next, persisting in a sanguine and grandiose offensive scheme to which many of his generals openly took exception, he found himself regarded with suspicion by his Government, and it was in the midst of a series of councils of war, inter-governmental negotiations, and internal incidents that he launched the attack of April 16 1917, a half victory which was the ruin of his hopes. Some weeks later he was dismissed from the command of the French armies. With the suspension of the offensive (which had already taken place), his command over the British forces had automatically ceased.

Later, Gen. Nivelle served as governor-general of Algeria.

Controversy of peculiar violence has naturally arisen in connexion with Nivelle's command and his offensive. On the general's side, Commandant de Civrieux's work is the principal source; on the other Jean de Pierrefeu's *La vérité sur l'affaire Nivelle* criticizes his actions from the standpoint of the Pétain school. Less definitely critical works, which contain the most important documents and deal with the political aspects of the case, are H. Galli, *L'offensive de 1917* and Mermeix, *Les Crises du Commandement* (pt. ii. *Nivelle et Painlevé*).

**NIXON, SIR JOHN ECCLES** (1857–1921), British general, was born Aug. 15 1857 and joined the army in 1875. He was transferred to the Indian cavalry in 1878, and he served in the Afghan War, the Mahsud Waziri expedition of 1881, the Chitral relief expedition in 1895, for which he was promoted brevet lieutenant-colonel, and the Tochi operations of 1897–8. He was promoted colonel in 1899, and he commanded a column during the later stages of the South African War and was given the C.B. for his services. Promoted major-general in 1904, he was inspector-general of cavalry in India from 1906–8, and he then held various higher commands in that country (being promoted lieutenant-general in 1909 and general in 1914) till in April 1915 he was sent to Mesopotamia to take charge of the campaign there. Under his auspices Gen. Townshend advanced successfully up the Tigris to Kut; but Nixon was largely responsible for the subsequent abortive attempt to reach Bagdad, which led to the retreat from Ctesiphon and to the investment of Kut. He fell ill towards the end of 1915 and quitted the theatre of war. In 1919 he was given the G.C.M.G. in recognition of his services four years earlier, and he retired in that year. He died at St. Raphael, France, Dec. 15 1921.

**NOBLE, SIR ANDREW, BART.** (1832–1915), British physicist and artillerist (*see* 19.730), died at Ardkinglas, Argyllshire, Oct.

22 1915. He was succeeded in the baronetcy by his eldest son George (b. 1859), two other sons, Saxton (b. 1863) and John (b. 1865), becoming prominently associated as directors with the management of their father's great engineering firm of Armstrong, Whitworth & Co. of Newcastle.

**NOGI, MARESUKE [KITEN]**, COUNT (1849–1912), Japanese general (*see* 19.733). After the campaign of 1904–5 he was decorated with the Imperial Order of the Rising Sun with Paulownia and the first-class Military Order of the Golden Kite, in recognition of his distinguished services. He and Countess Nogi committed suicide on Sept. 13 1912, when the state funeral of the Emperor Mutsu Hito was taking place, in sign of their devotion to their imperial master.

**NOLHAC, PIERRE DE** (1859– ), French scholar and author, was born at Ambert, Puy-de-Dôme, Dec. 15 1859. He was educated at the *lycées* of Puy and Rodez, and afterwards studied at Clermont and in the École des Hautes Études at Paris. He entered the Bibliothèque Nationale in 1885, became professor of philology at the École des Hautes Études in 1886, and was in 1892 made curator of the palace of Versailles, becoming hon. curator on resigning this post in 1921. He produced a series of works dealing with its history and associations, of which the chief are *Le Musée National de Versailles* (with A. Pératé, 1896); *Le Château de Versailles sous Louis XV.* (1898); *Les Jardins de Versailles* (1905); *Histoire du Château de Versailles* (1911); *Le Trianon de Marie Antoinette* (1914) and *Madame de Pompadour et des Arts* (1920). His other works, which deal with a great variety of subjects, include *Le Dernier Amour de Ronsard* (1882); *Lettres de Joachim du Bellay* (1883); *Erasme en Italie* (1888); *Petrarque et l'Humanisme* (1892; new edition 1907); besides several volumes of poems, and works on Nattier, Fragonard, Hubert Robert, Boucher, and Madame Vigée-Le Brun. He was made an officer of the Legion of Honour.

See P. Bouchaud, *Pierre de Nolhac et ses travaux* (1896).

**NOMOGRAPHY.**—The methods of graphic calculation may be divided into two main groups. (*a*) Those in which a more or less complicated geometrical construction is performed for the solution of an isolated problem. *Graphic Statics* (*see* 17.960) may be instanced as an example of this group. (*b*) Those in which all the solutions of a formula which are likely to be required are embodied in a permanent diagram with figured scales, drawn once for all, and read simply by the intersection of lines or the alignment of points on it.

The methods grouped under (*a*) do not lend themselves readily to concise and useful generalization; they can in fact only be dealt with satisfactorily as they occur in direct connexion with a particular subject. Those of group (*b*), however, the application of which in scientific and engineering work generally has developed considerably in recent years, can be successfully generalized, and they form the subject of this article.

It was M. d'Ocagne who, in his *Nomographie: Les calculs usuels effectués au moyen des abaques* (1891), invented the word *Nomographie—i.e.* the graphical presentment of laws—to describe the theory, and the word *Nomogramme* to describe the diagrams resulting from the application of these methods.

The English forms *Nomography* and *Nomogram* have now come into general use with similar meanings.

Although the invention and introduction of some of the methods utilized date back to a remote period, there can be no dispute as to the predominatingly important position to be assigned to the work of d'Ocagne as far as the generalization and systematization of the modern treatment are concerned.

The exposition of the main principles given in this article follows the lines laid down in his works.

1. *Notation.*—Following d'Ocagne the different variables appearing in an equation or formula will be denoted by $z_1, z_2, z_3, \ldots$, and the letters $f$, $g$, $h$, with appropriate subscripts, will be used to denote functions of these variables. Thus $f_1$, $g_1$, $h_1$, will denote different functions of $z_1$; $f_2$, $g_2$, $h_2$, different functions of $z_2$; $f_{12}$ a function of $z_1$ and $z_2$, and so on.

2. *Graphic Representation of a Two-Variable Formula in Cartesian Coördinates.*—With the functional notation explained above, the most general expression for an equation connecting two variables $z_1$, $z_2$, is,

$$f_{12}=0.$$

In the case of a practical formula, supposing $z_2$ to be the quantity which usually has to be determined for values of $z_1$, we as a rule have the equation in the *explicit* form,

$$z_2=f_1.$$

Taking the rectangular axes $Ox$, $Oy$ (fig. 1) we construct the curve C, the "graph" of

$$z_2=f_1$$

the abscissa $x$ and ordinate $y$ of any point on this curve representing corresponding values of $z_1$, $z_2$ respectively.

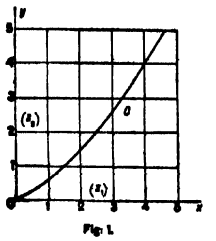

Fig. 1.

Suitable scales are selected for $z_1$ and $z_2$, according to the size of the diagram and the range of values of $z_1$, $z_2$ required.

Then, denoting by $\mu_1$, $\mu_2$ the units of the scales $(z_1)$, $(z_2)$,

$$x=\mu_1 z_1$$
$$y=\mu_2 z_2$$

define the graduations of the scales $(z_1)$, $(z_2)$ along $Ox$, $Oy$.

If any two corresponding values of $z_1$, $z_2$ are taken and parallels to $Ox$, $Oy$ drawn through the appropriate graduations on their respective scales, the intersection of these two straight lines gives a point on the curve.

Proceeding in this way with different corresponding values of $z_1$, $z_2$, the necessary number of points on the curve to enable it to be constructed with sufficient accuracy are obtained.

Having constructed the curve in this manner, the value of $z_2$ corresponding to any value of $z_1$ is obtained by following the parallel to $Oy$ through the given value of $z_1$ on the scale $(z_1)$ till it cuts the curve, and then following the parallel to $Ox$ through this point till it cuts the scale $(z_2)$ at a certain graduation. This graduation gives the value of $z_2$ required.

In order to save the trouble of having to draw the parallels on the diagram each time a reading is required, we construct a sufficient number once for all through the graduations of the scales $(z_1)$, $(z_2)$ so that the eye can follow them and, if necessary, interpolate between them to read the corresponding values.

Looking at the matter in a slightly different way,

$$x=\mu_1 z_1$$
$$y=\mu_2 z_2$$

may be considered as defining two systems $(z_1)$, $(z_2)$ of parallel straight lines at right-angles to each other, forming a *rectangular network*, the vertical and horizontal "meshes" of which are "figured" to correspond with the graduations of the scales through which they are drawn.

For any two values of $z_1$, $z_2$ which satisfy

$$z_2=f_1$$

we will then have two corresponding straight lines in this network which will intersect on the curve

$$z_2=f_1.$$

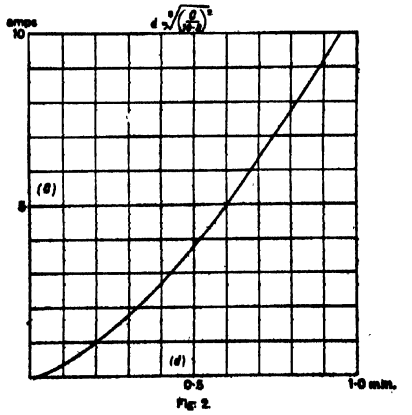

Fig. 2.

In practice the familiar "squared paper," already prepared with rulings at intervals of a millimetre or a tenth of an inch, is largely employed for work of this sort. Fig. 2 shows such a diagram constructed for the electrical formula

$$d=\sqrt[3]{\left(\frac{C}{K}\right)^2}$$

giving the current (C) in amperes which will fuse a wire of diameter $d$ mm., K being a constant depending on the metal of the wire. In this case the diagram has been constructed for lead wire (K = 10·8) of thickness up to 1 mm., and

$$z_1=d, \qquad \mu_1=50 \text{ mm.}$$
$$z_2=C, \qquad \mu_2=5 \text{ mm.}$$

3. *Graphic Representation of a Two-Variable Formula by Means of Two Adjacent Scales.*—The method described in §2 is the most

straightforward way, from the point of view of construction, of representing the formula graphically, but in practice it will frequently be found that two rectilinear scales side by side are more convenient, as they are more compact and quicker and easier to read, the eye not having to follow the line up from one graduation to the curve, and then along to the other graduation.

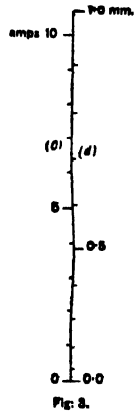

Fig. 3.

Fig. 3 has been constructed from fig. 2 to bring out these points. The scale ($z_2$) is the same, while the position of any graduation of the scale ($z_1$) is obtained by dropping a perpendicular to the scale ($z_2$) from the point on the curve in fig. 2 where the vertical line through any value of $z_1$ cuts it.

The two adjacent scales can, however, be constructed directly without the intermediary of a diagram in cartesians, by introducing the idea of the *functional scale*, which also figures largely in subsequent applications.

If $u$ is the distance of any graduation of the scale ($z_2$) from the zero, $\mu$ the unit employed,

$$u = \mu z_2$$

gives the graduations of the *regular* or *evenly divided* scale ($z_2$), in which for equal intervals between the values of $z_2$, the intervals between the graduations on the scale are equal.

For the distance of any graduation on the scale ($z_1$) from the zero we have

$$u = \mu f_1$$

defining the *functional scale* ($z_1$), in which the graduations are no longer equally spaced for equal intervals in the value of the variable $z_1$, but the segments cut off are proportional to the function $f_1$, although figured with the corresponding values of $z_1$.

4. *Graphic Representation of a Three-Variable Formula in Cartesian Coördinates.*—The equation connecting the three variables $z_1$, $z_2$, $z_3$ of a formula dealing with three variable quantities may, with our notation, be written, in its most general form

$$f_{123} = 0.$$

We take one of the variables, $z_3$ say, and give it in turn different values, starting with the lowest value required, and increasing by equal intervals. For each of these values we can construct a curve, as in §2, traced on the network defined by

$$x = \mu_1 z_1$$
$$y = \mu_2 z_2$$

Proceeding in this way for a suitable number of values of $z_3$, a system of *isoplethic curves* or *isopleths* is obtained. Along each of these curves $z_3$ has a constant value, and we mark this value against the curve. Such a diagram is seen schematically in fig. 4.

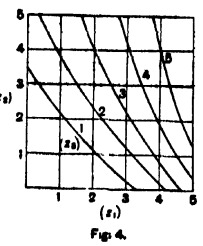

Fig. 4.

In order to find the value of $z_3$ corresponding to given values of $z_1$, $z_2$ we take a vertical line through the value of $z_1$ and a horizontal straight line through the value of $z_2$. We then note on what line of the system ($z_3$) the intersection of these two straight lines falls; if it falls between two lines, interpolation by eye is necessary to judge the intermediate value.

To put it more generally and concisely—*for values of $z_1$, $z_2$, $z_3$ which satisfy the given equation, the three corresponding lines of the systems ($z_1$), ($z_2$), ($z_3$) meet in a point.*

Hence the term "Intersection Nomogram" used to describe diagrams of this class, as contrasted with the "Alignment Nomogram" which will be dealt with later.

The systems of figured lines which it is necessary to employ in diagrams of this sort will in practice be found to render the reading troublesome in comparison with the reading of a simple graduated scale. The intersection of three lines has to be followed back to the place where their values are marked, and the interpolation by eye between the curves is difficult, while if the number of lines is increased to facilitate interpolation, the complication and confusion of the whole diagram are increased.

For these reasons, where the form of the equation renders it possible, it is frequently preferable to employ the methods of representation which will be described later.

5. *Principle of Anamorphosis.*—In the method of representation of the equation

$$f_{123} = 0$$

described in 4, we took, corresponding to the variables $z_1$, $z_2$, evenly divided scales along ox, oy.

Suppose that instead of this we take the functional scales

$$x = \mu_1 f_1$$
$$y = \mu_2 f_2.$$

Instead of the network with evenly spaced meshes corresponding to the evenly divided scales previously employed, we shall now have a network with unevenly spaced meshes on which the lines of the system will be altered in shape.

Such a transformation, known as an *anamorphosis*, is only of advantage when it leads to a better arrangement or simplification of the diagram. Thus it may be resorted to to space out the isopleths which would otherwise be too close together, or to make the curves which constitute them easier to draw and more convenient for interpolation. A particular case of frequent practical importance is that in which an anamorphosis can transform the isopleths into straight lines. This is best illustrated by an example.

Consider the formula

$$R = 3{\cdot}34\,\frac{V^2}{D}$$

connecting the retarding force in percentage weight of a train (R), with the speed in miles per hour (V), and the distance of the stop in feet (D).

Taking

$$z_1 = D$$
$$z_2 = V$$
$$z_3 = R$$

(*a*). Fig. 5 shows the representation on the lines of §4, the system (R) consisting of the parabolas

$$\left(\frac{y}{\mu_2}\right)^2 = \frac{R}{3{\cdot}34}\left(\frac{x}{\mu_1}\right)$$

arranged on the regular network

$$x = \mu_1 D$$
$$y = \mu_2 V$$

with $\mu_1 = 0{\cdot}25$ mm., $\mu_2 = 0{\cdot}625$ mm.

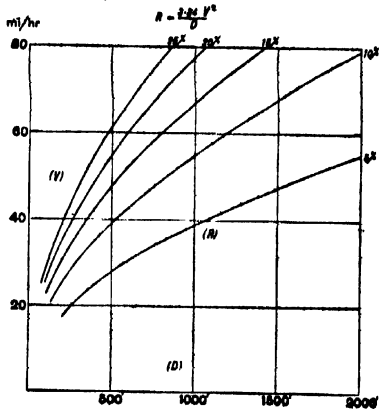

Fig. 5.

(*b*). If now instead of the network in (*a*), we employ the network

$$x = \mu_1 D$$
$$y = \mu_2 V^2$$

we obtain for the system (R) a system of straight lines

$$\frac{y}{\mu_2} = \frac{R}{3{\cdot}34}\left(\frac{x}{\mu_1}\right)$$

radiating from the origin (fig. 6).

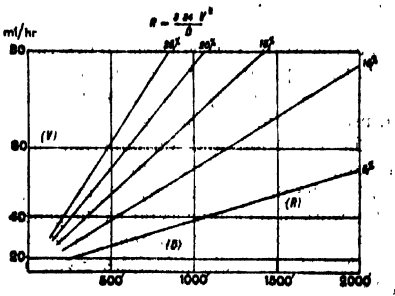

Fig. 6.

(*c*). Writing the formula

$$\log D - 2\log V + \log R - \log 3{\cdot}34 = 0$$

and employing the network

$$x = \mu_1 \log D$$
$$y = 2\mu_2 \log V$$

we obtain (fig. 7) for (R) a system of parallel straight lines

$$\frac{x}{\mu_1} - \frac{y}{\mu_2} + \log R - \log 3{\cdot}34 = 0.$$

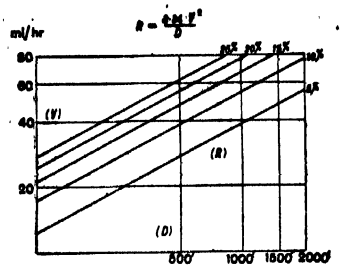

Fig. 7.

A logarithmic anamorphosis as illustrated in (*c*) is so frequently resorted to in practice that paper already ruled with a logarithmic network can be obtained commercially and is largely employed.

6. *Graphic Representation of a Three-Variable Formula in Parallel Coördinates.*—The preceding sections have dealt with Intersection Nomograms in which the answer is read from the intersection of lines in a point. For certain types of formulae, however, a representation is possible in which the three variables are arranged along three scales, and the answer is read by the alignment of points on these scales. Such an arrangement, an "Alignment Nomogram," is possible only when a diagram for the formula can be constructed, in cartesian coördinates, which consist of three systems of straight lines.

Defining the three systems of straight lines in cartesian coördinates by

$$\begin{aligned} xf_1+yg_1+h_1&=0\\ xf_2+yg_2+h_2&=0\\ xf_3+yg_3+h_3&=0 \end{aligned}$$

corresponding to the three variables $z_1$, $z_2$, $z_3$, we arrive at an equation for the formula which is most conveniently expressed in determinant notation

$$\begin{vmatrix} f_1 & g_1 & h_1\\ f_2 & g_2 & h_2\\ f_3 & g_3 & h_3 \end{vmatrix}=0 \qquad \text{(1)}.$$

For further investigation it is necessary to introduce the idea of *Parallel Coördinates* referred to two *parallel axes*, so that a point is represented by an equation of the first degree.

These coördinates are defined as follows:—If a straight line MN (fig. 8) cuts two parallel axes A*u*, B*v* (A and B being the origins of the axes) in M and N, the coördinates of the straight line are

$$u=\text{AM}, \quad v=\text{BN}.$$

Any equation of the first degree

$$au+bv+c=0$$

will represent a point, and to determine this point it is sufficient to know two solutions of the equation, and take the intersection of the straight lines resulting from these two solutions.

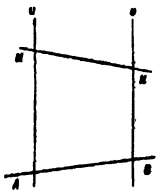

Fig. 8.

Putting $v=0$, $u=-\frac{c}{a}$

$u=0$, $v=-\frac{c}{b}$

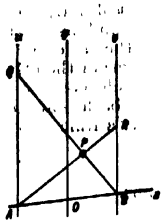

Fig. 9.

Along the axes A*u*, B*v* (fig. 9) take

$$\text{AQ}=-\frac{c}{a}, \quad \text{BR}=-\frac{c}{b}$$

The intersection of the straight lines AR, BQ in P will then give the point required, the point

$$au+bv+c=0$$

This correspondence of points to straight lines and *vice versa*, according as to whether cartesian or parallel coördinates are employed for the geometrical interpretation, is an example of the *Principle of Duality*. As an alternative to a diagram composed of straight lines there is a correlative diagram composed of points, and if three straight lines intersect in a point in the first diagram, the three points in the second will lie on a straight line.

Effecting such a *dualistic transformation* the three systems of straight lines

$$\begin{aligned} xf_1+yg_1+h_1&=0\\ xf_2+yg_2+h_2&=0\\ xf_3+yg_3+h_3&=0 \end{aligned}$$

will now be represented by three systems of points

$$\begin{aligned} uf_1+vg_1+h_1&=0\\ uf_2+vg_2+h_2&=0\\ uf_3+vg_3+h_3&=0 \end{aligned}$$

forming three scales arranged along a straight line or a curve, according as to whether the straight lines of the correlative system meet in a point or not,[1] and when three points are taken on these scales whose graduations correspond to three values of $z_1$, $z_2$, $z_3$ satisfying (1), the three points will lie on a straight line, since the correlative straight lines meet in a point.

Hence to use such a diagram (shown schematically in fig. 10) we join any two values of two of the variables on their respective scales by a straight line, and the point of intersection of this straight line with the third scale gives the corresponding value of the third variable.

It will not be necessary actually to draw the straight line on the diagram; a piece of thread stretched across it will give the alignment, or a strip of transparent celluloid, having a straight line engraved down the centre, may be employed for the same purpose.

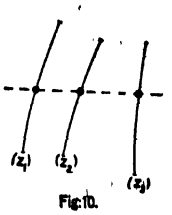

Fig. 10.

Given a diagram consisting of straight lines only, representing a three-variable formula in cartesian coördinates, the correlative diagram representing the same formula in parallel coördinates can be constructed geometrically without knowing the analytical expression of the formula represented.

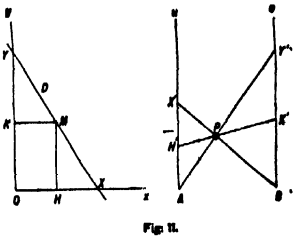

Fig. 11.

Let D (fig. 11) be a straight line of the left-hand diagram. Take a point M on this straight line whose cartesian coördinates are OH, OK.

The correlative straight line H'K' will be one whose parallel coördinates are

$$\text{AH}'=\text{OH}, \quad \text{BK}'=\text{OK}.$$

Taking in this way the correlative straight lines to any two points on the straight line D, we get by their intersection the point P, correlative to the straight line D.

Thus we might take BX', AY', the correlatives of X and Y, the points where the straight line D cuts the axes Ox, Oy, making

$$\text{AX}'=\text{OX}, \quad \text{BY}'=\text{OY}.$$

Proceeding in this way we can replace all the straight lines of the intersection diagram by points.

As an example we have taken the Intersection Nomogram, fig. 6, and constructed from it an Alignment Nomogram, fig. 12.

Suppose, for instance, we want to know the value of R for V = 70 m./h., D = 1,100 ft. All that it is necessary to do in fig. 12 is to join 70 on the (V) scale to 1,100 on the (D) scale. This straight line will be found to cut the (R) scale at 15 % (see transverse line in fig. 12), the required value of R.

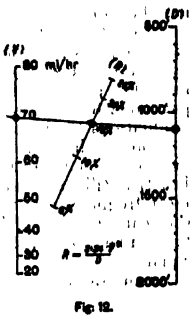

Fig. 12.

Comparing the two figures the advantages of the Alignment Nomogram will be evident. The disadvantages referred to in §4 have disappeared, for there is no tracing back along a line to read its graduation, and any interpolation by eye is only necessary on simple graduated scales.

Proceeding to the direct construction of Alignment Nomograms without the preliminary construction of an Intersection Nomogram, certain types will now be considered which are particular cases of the general equation (1).

*Type A—Nomograms with Three Parallel Rectilinear Scales.* If the formula to be represented can be put in the form

$$f_1+f_2+f_3=0 \qquad \text{(2)}$$

the three systems of points $(z_1)$, $(z_2)$, $(z_3)$ can be arranged on three parallel straight lines.

For the systems $(z_1)$, $(z_2)$ we take the functional scales

$$u=\mu_1 f_1 \qquad \text{(3)}$$
$$v=\mu_2 f_2 \qquad \text{(4)}$$

along the two parallel axes A*u*, B*v* (fig. 13).

Eliminating $f_1$, $f_2$ between (2), (3) and (4) gives us for $(z_3)$

$$\mu_2 u+\mu_1 v+\mu_1\mu_2 f_3=0 \qquad \text{(5)}.$$

It is now convenient to revert to cartesian coördinates, taking as origin O, the midpoint of AB, the axis of *x* along AB, the axis of *y* parallel to A*u* or B*v* (*see* fig. 9). Also let OB be denoted by $\lambda$.

With these axes (5) will denote the system of points,

$$x=\lambda\frac{\mu_1-\mu_2}{\mu_1+\mu_2}, \quad y=\frac{\mu_1\mu_2 f_3}{\mu_1+\mu_2}$$

[1] Parallel straight lines of course fulfil this condition, and lead to a rectilinear scale as they have a common point at infinity.

The expression for $x$ being constant we see that the points are arranged along a straight line $Cw$ parallel to $Au$, $Bv$, and this straight line cuts AB at a point C such that

$$\frac{CA}{CB} = -\frac{\mu_1}{\mu_2}$$

Then writing for the scale $(z_3)$ on $Cw$

$$w = -\mu_3 f_3$$

as $w$ is the same as $y$ we have

$$\mu_3 = \frac{\mu_1\mu_2}{\mu_1+\mu_2}$$

or

$$\frac{1}{\mu_3} = \frac{1}{\mu_1} + \frac{1}{\mu_2}$$

In the particular case where $\mu_1 = \mu_2$ we will have

$$\mu_3 = \frac{\mu_1}{2} = \frac{\mu_2}{2}$$

To recapitulate, the practical procedure is shortly as follows:—Select suitable axes $Au$, $Bv$ and suitable units $\mu_1$, $\mu_2$. Draw $Cw$ dividing AB in the ratio $\frac{\mu_1}{\mu_2}$, and determine the unit $\mu_3$ by the relation

$$\frac{1}{\mu_3} = \frac{1}{\mu_1} + \frac{1}{\mu_2}$$

Construct along $Au$, $Bv$, $Cw$, respectively the scales

$$u = \mu_1 f_1$$
$$v = \mu_2 f_2$$
$$w = \mu_3 f_3$$

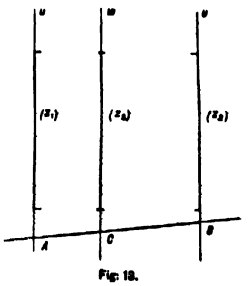

Fig. 13.

Any straight line drawn across these three will then cut them at corresponding values of $z_1$, $z_2$, $z_3$ as defined by (2).

As a rule we arrange the diagrams so that the scale of the variable, which has generally to be determined in terms of the other two, lies between their scales, as this conduces to greater accuracy in reading.

It is not necessary for the origins A, B, C, to appear on the diagram unless they are required for the range of the variables for which the formula is to be employed. The scales can be quite easily constructed without them, starting from the lowest value required. It will be seen that the freedom of choice of axes and units renders this method an exceedingly flexible one. Examining the range of the variables required for the practical use of the particular formula, we can arrange the scales and the size of their graduations to the best advantage.

Among other things, we wish to avoid the reading straight line making too acute an angle with the scales, as this leads to inaccuracy. Practice will soon enable the best disposition to be seen, but it will most frequently be found convenient to make the useful parts of the scales $(z_1)$, $(z_2)$ about the same length and about the same distance apart, so that the complete diagram is roughly contained in a square.

As an example of Type A, the formula

$$d = \sqrt[4]{\left(\frac{C}{K}\right)^3}$$

already referred to in §2 can be taken, supposing that it is now desired to construct a nomogram to show different values of K, instead of a single curve for a constant value of K.

The formula can be reduced to Type A by writing it

$$\log d + \tfrac{3}{4}\log K - \tfrac{3}{4}\log C = 0$$

and taking

$$z_1 = d, \qquad f_1 = \log d$$
$$z_2 = K, \qquad f_2 = \tfrac{3}{4}\log K$$
$$z_3 = C, \qquad f_3 = -\tfrac{3}{4}\log C$$

the scales are all logarithmic scales, differing only as regards their unit.

Take any convenient logarithmic scale that may be available (say that of a slide rule) and by means of it graduate the scales $(d)$ and (K) on two convenient parallel axes (fig. 14).

We can then determine the point C = 10 on the scale (C) by the cross alignments

$$d = 1, \qquad K = 10$$
$$d = 2{\cdot}5, \qquad K = 80$$

for both of which C = 10.

The support of (C) is then a straight line parallel to the axes through this point, and we can graduate it by noticing that for C = K, we always have $d = 1$.

The alignment of $d = 1$ with K = 20, 30, 40, 50, in turn, then gives the points C = 20, 30, 40, 50, ....

Suppose now that we want to know the current which will fuse an aluminium (K = 59) wire 0·3 mm. diameter. The straight line joining 0·3 on the $(d)$ scale to 59 on the (K) scale (see dotted line, fig. 14) cuts the (C) scale at about 9·5 amp., the required current.

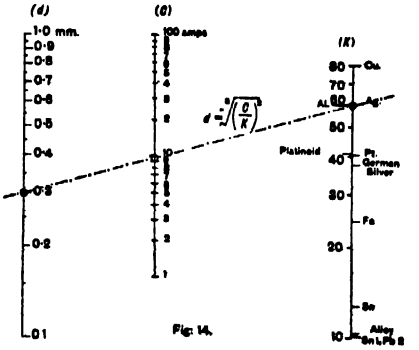

Fig. 14.

*Type B.—Nomograms with three rectilinear scales, two of which are parallel.* If the formula to be represented can be put in the form

$$f_1 + f_2 h_3 = 0 \qquad (6)$$

it can be represented by two systems of points $(z_1)$, $(z_2)$ arranged along two parallel straight lines, and a third system arranged along a straight line making an angle with the other two.

As before, we take the functional scales

$$u = \mu_1 f_1$$
$$v = \mu_2 f_2$$

along the parallel axes $Au$, $Bv$ (fig. 15).

We then have for the system $(z_3)$

$$\mu_2 u + \mu_1 h_3 v = 0$$

which with our usual axes defines the system of points

$$x = \lambda\frac{\mu_1 h_3 - \mu_2}{\mu_1 h_3 + \mu_3}, \quad y = 0$$

so that the points of the system are arranged along AB.

The scale $(z_3)$ can be graduated by the use of the above expression for $x$, or from a double-entry table of corresponding values of $z_1$, $z_2$, $z_3$, by successive alignments of pairs of values of $z_1$, $z_2$ corresponding to any graduation $z_3$. Thus if $a$ and $c$ are a pair of values of $z_1$ and $z_2$ which correspond to the value $b$ of $z_3$, we join $ac$ to cut AB at $b$, which gives the graduation of the scale for the value $b$.

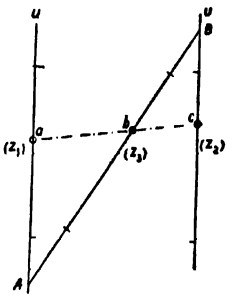

Fig. 15.

If A and B do not appear on the diagram the support of the scale $(z_3)$ can be drawn by making use of the relation, that if $\delta_1$, $\delta_2$ are the distances of a point on $(z_3)$ from $Au$, $Bv$, we have

$$\frac{\delta_1}{\delta_2} = -\frac{\mu_1 h_3}{\mu_2}$$

On the completed diagram any straight line drawn across the three scales will cut them at corresponding values of $z_1$, $z_2$, $z_3$ as defined by (6).

The scale $(z_3)$ will lie between or outside the scales $(z_1)$, $(z_2)$ according as to whether $h_3$ is positive or negative, and, as in the previous type, it is as a rule best to arrange that the scale of the variable, which generally has to be determined in terms of the other two, lies between their scales; $h_3$ can always be made positive or negative as desired, altering if necessary the signs of both $f_3$ and $h_3$.

As an example of Type B take Sir Benjamin Baker's Rule for the weight of rails

$$W = 17\sqrt[3]{(L + 0{\cdot}0001\ Lv^3)^3}$$

where L = Greatest load on one driving wheel in tons.
$v$ = Maximum velocity in miles per hour.
W = Weight of rails in lb. per yard.

Writing the formula

$$L - \left(\frac{1}{1+0{\cdot}0001v^3}\right)\left(\frac{W}{17}\right)^3 = 0$$

and taking

$$z_1 = L, \quad f_1 = L$$
$$z_2 = v, \quad f_2 = -\frac{1}{1+0{\cdot}0001v^3}$$
$$z_3 = W, \quad h_3 = \left(\frac{W}{17}\right)^3$$

construct the scales

$$u = \mu_1 f_1 = \mu_1 L$$
$$v = \mu_2 f_2 = -\mu_2\left(\frac{1}{1+0{\cdot}0001v^3}\right)$$

along two convenient parallel axes. The scale (L) is an evenly divided scale, and to graduate the scale ($v$) a series of values of $v$ and $f_3$ are calculated

| $v=$ | 20 | 30 | 40 | 50 | 60 | 70 | 80 |
|---|---|---|---|---|---|---|---|
| $f_3=$ | −0·961 | −0·917 | −0·862 | −0·800 | −0·735 | −0·671 | −0·610 |

The support of the scale (W) is the straight line joining the zero of the (L) scale to the zero of the $f_3$ scale. This latter zero is at an inconveniently great distance from the top graduation on the ($v$) scale, but the support can readily be obtained without the actual use of the zeros of the $f_1$ and $f_2$ scales by the use of the formula

$$\frac{\delta_1}{\delta_2}=-\frac{\mu_1 h_3}{\mu_2}$$

referred to above, or by a cross alignment in the following way:—Take W = 100 and work out L for $v$ = 60 and 80. The straight lines joining these two values of L and $v$ will intersect at the point 100 on the W scale. Joining this point to the zero of the (L) scale gives the support, and the remainder of the scale can be graduated by taking $v$ = 50 say, and working out L for W = 20, 30, 40, 50.... Joining 50 on the ($v$) scale to these values of the (L) scale in turn, will give an intersection on the support for the corresponding graduations of the (W) scale.

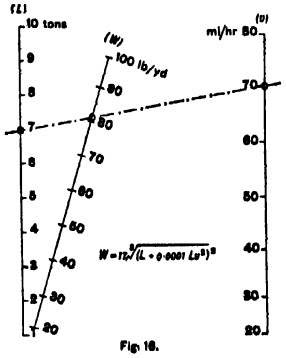

Fig. 16.

The completed diagram is shown in fig. 16. To use it suppose, for instance, we require the value of W for L = 7 tons, $v$ = 70 m./hour. The straight line joining 7 on the (L) scale to 70 on the ($v$) scale (see dotted line, fig. 16) cuts the (W) scale at about 82 lb./yd., the required value.

*Type C.—Nomograms with two parallel rectilinear scales and one curvilinear scale.* If the formula to be represented can be put in the form

$$f_1g_3+f_3h_3+f_3=0 \qquad (7)$$

it can be represented by two systems of points ($z_1$), ($z_2$), arranged along two parallel straight lines, and the third system ($z_3$) arranged along a curve.

As in the preceding types we take functional scales

$$u=\mu_1 f_1$$
$$u=\mu_2 f_2$$

along the parallel axes A$u$, B$v$ (fig. 17).

We then have for the system ($z_3$)

$$\mu_3 g_3 u+\mu_1 h_3 v+\mu_1\mu_2 f_3=0$$

which with our usual axes defines the system of points

$$x=\lambda\frac{\mu_1 h_3-\mu_2 g_3}{\mu_1 h_3+\mu_2 g_3}, \qquad y=\frac{-\mu_1\mu_2 f_3}{\mu_1 h_3+\mu_2 g_3}$$

and we can determine any number of points on the system ($z_3$) by means of these equations, or by a series of cross alignments. This latter method is especially indicated in cases in which a double-entry table of corresponding values of $z_1$, $z_2$, $z_3$, is already available.

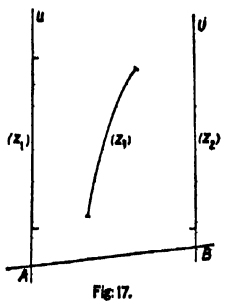

Fig. 17.

Proceeding by whichever of these ways is most convenient, we can obtain the complete scale ($z_3$), tracing the curvilinear support through the points determined.

As before it is advantageous, where the variable $z_3$ is generally the unknown, for the scale ($z_3$) to lie between the scales ($z_1$), ($z_2$). This will be the case if

$$\frac{h_3}{g_3}$$

is positive, and this can always be arranged, if necessary, changing the signs of both $f_3$ and $h_3$.

Having constructed the scales ($z_1$), ($z_2$), ($z_3$) as described above, any straight line drawn across them will cut the three scales at corresponding values of $z_1$, $z_2$, $z_3$ as defined by (7).

As an example of Type C take the formula used for the thickness of cast-iron pipes in waterworks,

$$t=0\cdot000125\ P\ d+0\cdot15\sqrt{d}$$

where

$t$ = Thickness of metal in inches.
P = Pressure of water in pounds/inch.
$d$ = Internal diameter of pipe in inches.

Writing this,

$$0\cdot000125\ P\ d-t+0\cdot15\sqrt{d}=0$$

and putting

$$z_1=P,\ f_1=P$$
$$z_2=t,\ f_2=t$$
$$z_3=d,\ f_3=0\cdot15\sqrt{d},\ g_3=d,\ h_3=1$$

we see that it is of type C.

We construct the scales

$$u=\mu_1 P$$
$$v=\mu_2 t$$

along two convenient parallel axes (fig. 18).

We then determine sufficient points on ($d$), by cross alignments, to draw the curve and graduate the scale.

When P is zero,

$$t=0\cdot15\sqrt{d}$$

giving us an easily calculated series of alignments for $d$ = 5, 10, 15...

For the cross alignments it will be convenient to take P = 100, and calculate $t$ for $d$ = 5, 10, 15, ... as before.

Suppose now we wish to know the thickness of a pipe of 30-in. bore to stand a pressure of 130 lb./in. Joining 130 on the (P) scale to 30 on the ($d$) scale, and producing the straight line to cut the ($t$) scale (see dotted line, fig. 18), we get, at the point of intersection, the required value $t$ = 1·3 in.

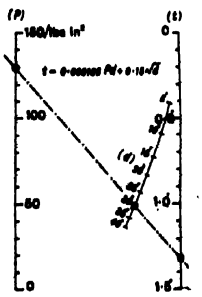

Fig. 18.

7. *Graphic Representation of Formulae with more than Three Variables.* (i.) *Double Alignment Nomograms.*—Certain types of formulae containing four variables can be dealt with by breaking them up into two or three variable formulae with a common auxiliary variable.

Consider for instance a formula which can be written in the form

$$f_1+f_2=f_3+f_4 \qquad (8).$$

Introducing an auxiliary variable $z_5$ we can construct two partial nomograms

$$f_1+f_2=z_5 \qquad (9)$$
$$f_3+f_4=z_5 \qquad (10)$$

of Type A, having the scale ($z_5$) in common.

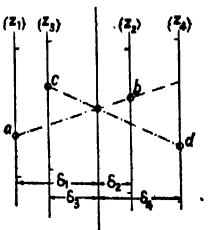

Fig. 19.

Such an arrangement is shown schematically in fig. 19, the central line representing the auxiliary scale.

If we take values of $z_1$, $z_2$, $z_3$, $z_4$ satisfying equation (6), the alignment of $z_1$ with $z_2$, and of $z_3$ with $z_4$ will intersect on the scale ($z_5$). The central line need not be graduated as it is only required as a *reference line*, the nomogram being read in the following way:—

Suppose we require the value of $z_4$ for

$$z_1=a,\quad z_2=b,\quad z_3=c.$$

Join $a$ on ($z_1$) to $b$ on ($z_2$) cutting the reference line at $e$. Join $c$ on ($z_3$) to $e$ and produce to cut ($z_4$) in $d$, which will give the corresponding value of $z_4$.

Such a nomogram from the way in which it is read is termed a Double Alignment Nomogram.

It will be noticed that as the unit of ($z_5$) is the same in both (9) and (10) we must have the relationship

$$\frac{1}{\mu_1}+\frac{1}{\mu_2}=\frac{1}{\mu_3}+\frac{1}{\mu_4}$$

while the distances of the scales from the reference line (fig. 19) will be given by

$$\frac{\delta_1}{\delta_2}=-\frac{\mu_1}{\mu_2}, \qquad \frac{\delta_3}{\delta_4}=-\frac{\mu_3}{\mu_4}$$

Hence for the practical construction we graduate any of the three scales, ($z_1$), ($z_2$), ($z_3$), say, from three conveniently chosen origins on the supports of their scales. We then determine a point on the scale ($z_4$) by means of four values of $z_1$, $z_2$, $z_3$, $z_4$, ($a$, $b$, $c$, $d$, say) which satisfy equation (8).

The alignment of $c$ and the intersection of the alignment $ab$ with the reference line then determine the point $d$ on the scale ($z_4$), and as we know $\mu_4$ we can construct the scale ($z_4$) completely.

As an example take the formula for the discharge of gas in pipes,

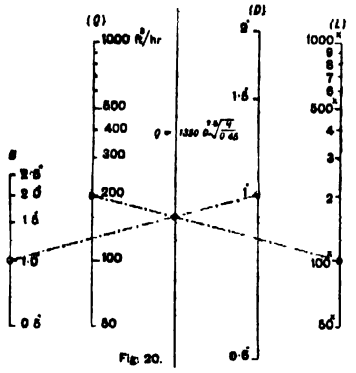
$$Q=1350\ D^{2\cdot5}\sqrt{\frac{H}{0\cdot45L}}$$

where

L = Length of pipe in yards.
D = Diameter of pipe in inches.
H = Head of water in inches equivalent to the pressure.
Q = Quantity of gas discharged in cub. ft. per hour.

Writing it

$$\log Q+\tfrac{1}{2}\log L=2\cdot5\log D+\tfrac{1}{2}\log H+\text{const.}$$



We put

$$z_1=Q,\ z_2=L,\ z_3=H,\ z_4=D.$$

Fig. 20 shows the resulting nomogram constructed with

$$\mu_1 = \tfrac{1}{2}\mu_2 = \tfrac{1}{2}\mu_3 = \mu_4$$

Suppose now that we want to know the rate of discharge from a 100-yd. pipe of 1-in. bore, with a head of water of 1 in.

Join 1 on the (D) scale to 1 on the (H) scale. Join the point where this straight line cuts the reference line to 100 on the (L) scale, and produce the straight line backwards to cut the (Q) scale at 201 ft./hour (see dotted lines, fig. 20), the required rate of discharge.

These Double Alignment Nomograms can be constructed by combining any two of the types, A, B, or C where the four-variable formula can be written in the appropriate form.

Take for instance the formula

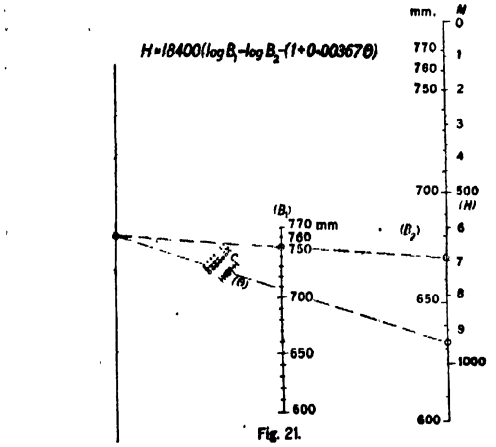
$$H = 18{,}400\ (\log B_1 - \log B_2)\ (1 + 0{\cdot}00367\theta)$$

giving the difference in level (H metres) between two stations at which the barometric readings are $B_1$ and $B_2$ mm. respectively, the mean temperature being $\theta$°C. $\left(\theta = \frac{t_1 + t_2}{2}\right)$

Writing it

$$\frac{H}{18{,}400\ (1 + 0{\cdot}00367\theta)} = \log B_1 - \log B_2$$

it can be broken up into two partial nomograms of Type B and A respectively.



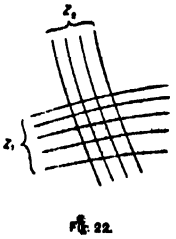


Fig. 21 shows the resulting nomogram, and, to illustrate its use, suppose $B_1 = 750$ mm., $B_2 = 670$ mm. and it is required to find H.

Join 670 on $(B_2)$ to 750 on $(B_1)$, and produce to cut the reference line. Join the point thus obtained on the reference line to +20 on $(\theta)$. This straight line produced will cut (H) at 935 mm. (see dotted line, fig. 21), the required difference in height.

(ii). *Combination of an Alignment Nomogram with a Network.*

Suppose we have a network $(z_1, z_2)$, composed of two systems of figured curves $(z_1)$, $(z_2)$ crossing each other (fig. 22).

If we take any point on this network, a curve of both systems will pass through this point, and we may assign to the point a value of both $z_1$ and of $z_2$, taking the values from the curves of the systems $(z_1)$, $(z_2)$ which intersect in the point. The point has thus in a sense two values and is termed a *binary point.*

The general equation in parallel coördinates of such a binary point will be of the form

$$f_{12} + g_{12}u + h_{12}v = 0$$

and its coördinates in cartesians with the usual axes will be

$$x = \lambda\frac{h_{12} - g_{12}}{h_{12} + g_{12}}, \qquad y = -\frac{\mu f_{12}}{h_{12} + g_{12}}$$

We can obtain the equations of the systems $(z_1)$, $(z_2)$ forming the network $(z_1, z_2)$ by eliminating in turn $z_2$ and $z_1$ between the above expressions for $x$ and $y$.

Consider now a formula that can be put in the form

$$f_1 g_{34} + f_3 h_{34} + f_{34} = 0$$

This can be represented by the rectilinear parallel scales

$$u = \mu_1 f_1$$
$$v = \mu_2 f_3$$

and the network

$$\mu_2 g_{34} u + \mu_1 h_{34} v + \mu_1\mu_2 f_{34} = 0$$

or

$$x = \lambda\frac{\mu_1 h_{34} - \mu_2 g_{34}}{\mu_1 h_{34} + \mu_2 g_{34}}, \qquad y = \frac{-\mu_1\mu_2 f_{34}}{\mu_1 h_{34} + \mu_2 g_{34}}$$

As an example take the Compound Interest Formula

$$M = PR^n$$

where P is the principal, M the amount, R the amount of £1 for one year at $r$ % per annum $\left(i.e.\ R = 1 + \frac{r}{100}\right)$, $n$ the number of years.

Writing it

$$\log P + n \log R - \log M = 0$$

and taking

$$z_1 = P, \quad f_1 = \log P$$
$$z_2 = n, \quad f_2 = n$$
$$z_3 = r, \quad f_{34} = -\log M$$
$$z_4 = M, \quad g_{34} = 1, \qquad h_{34} = \log R$$

the nomogram will consist of the parallel scales

$$u = \mu_1 \log P$$
$$v = \mu_2 n$$

and the network (r, M) defined by

$$\mu_2 u + \mu_1 \log R v - \mu_1\mu_2 \log M = 0$$

or in cartesians

$$x = \lambda\frac{\mu_1 \log R - \mu_2}{\mu_1 \log R + \mu_2}, \qquad y = \frac{\mu_1\mu_2 \log M}{\mu_1 \log R + \mu_2}$$

The expression for $x$ is independent of M, so that we have for $(r)$ a system of straight lines parallel to (P) and $(n)$.

For the system (M) we have, eliminating R between the above expressions for $x$ and $y$,

$$2\lambda y = \mu_1 \log M\ (\delta - x)$$

hence (M) consists of straight lines radiating from the point $x = \lambda$, $y = 0$ (*i.e.* the zero of the $n$ scale), and cutting the straight line $x = -\lambda$ (*i.e.* the P scale) at the points

$$y = -\mu_1 \log M$$

so that the lines of the system (M) are easily drawn from the graduations of (P).

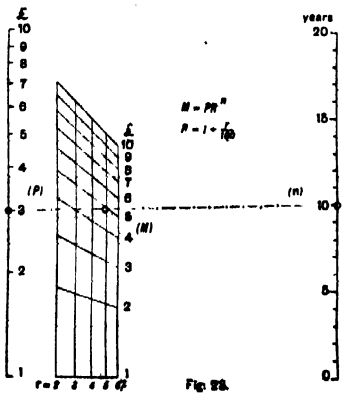

Fig. 23 shows the completed diagram. Suppose, for instance, we want to know the amount of £300 in 10 years at 5% compound interest. Joining 3 on the (P) scale to 10 on the $(n)$ scale, this straight line cuts the 5% line (see dotted line, fig. 23) at a point corresponding to the line £490 of the system (M).

**NORDICA, LILIAN** (1859–1914), American operatic singer (*see* 19.741), died in Batavia, Java, May 10 1914.

**NORFOLK, HENRY FITZALAN HOWARD,** 15TH DUKE OF (1847–1917), English statesman (*see* 19.744), died in London Feb. 11 1917. He was succeeded by the son of his second marriage, Bernard Marmaduke Fitzalan Howard (b. 1908).

LORD EDMUND TALBOT (b. 1855), brother of the 15th duke, became deputy earl marshal during the minority of the 16th duke. He had assumed in 1876 the name and arms of Talbot instead of Howard, and for many years was a prominent member of the Conservative party in the House of Commons, being Chief Whip from 1913 to 1921. In 1921 he was appointed Viceroy of Ireland and created a peer as Viscount Fitzalan; and he then resumed the family name of Howard.

**NORTH, SIR FORD** (1830–1913), English judge, was born at Liverpool Jan. 10 1830, the son of a solicitor. He was educated at Winchester and at University College, Oxford, where he took his degree in 1852. He was called to the bar in 1857, and became a Q.C. in 1877. In 1881 he was raised to the bench of the Queen's Bench division, but in 1883 was transferred to the Chancery division. He retired in 1900 and was created a privy councillor, but continued to sit as a member of the judicial committee of the privy council. He died at Carron, Ross, Oct. 13 1913.

**NORTH CAROLINA** (*see* 19.771).—The pop. in 1920 was 2,559,123, as compared with 2,206,287 in 1910, a gain of 352,836, or 16%. Somewhat fewer than one-third were negroes and 7,099 were foreign-born whites, representing 43 different nationalities. There was less foreign admixture than in the population of any other state. There were 490,370 persons living in cities of 2,500 or more, 240,753 in villages, and 1,828,000 in the open country, so that the state was still predominantly rural, 71% of the pop. living outside of incorporated towns, as against 76% in 1910. This is emphasized by the absence of any large city.

The following table shows the cities having a pop. in 1920 of 15,000 and their gain for the preceding decade:—

| City | 1920 | 1910 | Increase |
|---|---|---|---|
| Winston-Salem | 48,395 | 22,700 | 113·2 |
| Charlotte | 46,338 | 34,014 | 36·2 |
| Wilmington | 33,372 | 25,748 | 29·6 |
| Asheville | 28,504 | 18,762 | 51·9 |
| Raleigh | 24,418 | 19,218 | 27·1 |
| Durham | 21,719 | 18,241 | 19·1 |
| Greensboro | 19,861 | 15,895 | 25·0 |

In 1914 the Legislature passed a law providing for the registration of births, deaths, and their causes. Subsequently the death-rate steadily decreased, notably in the case of typhoid fever, where it fell from 35·8 per 100,000 to 10·6 in 1920. In the same period the death-rate from diphtheria was reduced from 22·3 per 100,000 to 9·5. The total death-rate was 12·9 per 1,000 in 1920, a rate lower than that of any of the older states. This was accompanied by the highest birth-rate of any registration state, 32·8 per 1,000 in 1920.

*Agriculture.*—The decade saw great improvements in agriculture, both in methods and crop yields. The tendency noted in 1910 toward smaller holdings continued. The number of farms in 1920 was 269,763 as against 253,725 in 1910, but there was a greater average value per farm. In 1919 the values of farm products were greatly inflated, but those of 1920 were not far from the average for 1915–20. The following table presents the more striking figures for 1920 as estimated by the U.S. Department of Agriculture:—

| Crop | Acres | Yield (bus.) | Value |
|---|---|---|---|
| Corn | 2,784,000 | 64,032,000 | $72,356,000 |
| Wheat | 724,000 | 8,471,000 | 17,789,000 |
| Oats | 180,000 | 3,960,000 | 3,802,000 |
| Rye | 96,000 | 912,000 | 1,733,000 |
| Potatoes | 56,000 | 5,040,000 | 7,157,000 |
| Sweet Potatoes | 101,000 | 10,605,000 | 12,090,000 |
| Tobacco | 582,000 | 384,120,000* | 97,182,000 |
| Hay | 897,000 | 1,310,000† | 30,130,000 |
| Cotton | 1,518,000 | 840,000‡ | 60,900,000 |
| Peanuts | 113,000 | 3,955,000 | 5,418,000 |

*Pounds. †Tons. ‡Bales.

The value of all crops in 1920 was estimated to be $412,374,000 as against $142,890,000 in 1909. The state in this respect stood eleventh in 1917, rose to fifth in 1918, to fourth in 1919, and dropped to sixth in 1920. Farm land increased in the average value per acre from $6.24 in 1900, $15.29 in 1910, to $63.00 in 1920. Trucking and fruit growing showed marked increase.

Live stock showed no striking increase except in the case of mules. The following table gives the comparative figures:—

FARM ANIMALS

| | 1920 | | 1910 | |
|---|---|---|---|---|
| | Number | Value | Number | Value |
| Mules | 236,000 | $44,840,000 | 174,711 | $23,709,000 |
| Horses | 183,000 | 27,999,000 | 166,151 | 18,428,000 |
| Milch Cows | 328,000 | 25,584,000 | 308,914 | 7,839,000 |
| Other Cattle | 394,000 | 13,908,000 | 391,947 | 4,711,000 |
| Swine | 1,575,000 | 31,500,000 | 1,227,625 | 4,638,000 |
| Sheep | 144,000 | 1,368,000 | 214,473 | 559,000 |

*Manufactures.*—The notable industrial development of the two preceding decades was continued between 1910 and 1920. In 1914 the industrial capital of the state was $253,842,000, and the value of manufactured products $289,412,000. No later figures were available in May 1921, but both the capital and the value of products were greatly increased by 1920. Cotton and tobacco manufacturing led. In 1920 there were nearly 550 cotton-mills in operation with 5,321,450 producing spindles. In tobacco manufacturing Winston-Salem and Durham held first and second places respectively among the cities of the world. The volume of the industry can be estimated from the fact that for the year 1919–20 the Federal stamp tax in the state yielded $108,457,156. The manufacturing of the state was highly diversified and there was a notable absence of concentration, there being many small establishments. The syndicating of cotton-mills was a pronounced movement during the years 1916–20. It followed the syndication of tobacco factories, fertilizer plants, and cotton-seed oil mills. Steam power was generally employed in the decade 1910–20, but there was increasing use of hydro-electric power. In 1920, 330,000 H.P. had been developed, and it was estimated that a million more were available for development.

*Forests and Mines.*—The total value of lumber and timber products in the state in 1914, the last year for which accurate figures were available in June 1921, was $39,631,573. It increased largely during the remainder of the decade. In spite of the ruthless lumbering operations of the past 40 years, it was estimated in 1920 that there was standing timber ready for the saw to the value of $167,450,000, with young growth valued at $192,300,000. Mineral products in 1917 were valued at $5,246,391, the more important being clay products and stone.

*Transportation.*—Railway development in the years 1919–20 was checked in 1914 and stopped completely in 1917 by the World War. Only 357 m. of new line and 217 m. of sidings were built, making a total mileage in 1920 of 4,997. In 1917 there were also 172 m. of electric road in operation. Marked improvements were made in the public highways. The Legislature of 1921 undertook the creation of a great state system by providing for the issue of $50,000,000 in bonds. The details of construction were in the hands of a highway commission established in 1917 and enlarged in 1921.

*Finance.*—The revenue of the state for general state purposes in 1919 was $7,647,482, while state, county, and school taxes together yielded a total of $18,912,000. The bonded debt of the state in 1920 was $9,603,000; of the counties, $23,198,226; and of the cities, $28,877,000, making a total of $61,678,226. In addition, there had been otherwise issued $12,000,000 for school buildings, and $24,000,000 voted for roads. The Legislature of 1921 authorized the bond issue already mentioned of $50,000,000 for state highways, as well as $6,000,000 as a state-aid loan fund for consolidated schools, and $6,745,000 for permanent improvements in the state's hospitals and institutions of higher learning. It also authorized the issue of $25,000,000 in local bonds, and $5,500,000 was issued by small cities prior to May 1 1921. The total indebtedness, actual and authorized, was on May 1 1921 about $200,000,000, nearly all incurred after 1910. This showed the willingness of the people of the state to tax themselves for community and commonwealth prosperity, a remarkable revolution in sentiment.

The taxation system of the state had long been condemned as ineffective and inequitable, and the Legislature of 1919 passed a law providing for assessment for taxation of all real and personal property at its actual value. This Act was accompanied by the submission to the people of constitutional amendments authorizing a general income tax, limiting the rate of combined state and county property taxes to $.15 per $100 of valuation, permitting a segregation of taxes for state purposes, and abolishing the existing equality between the tax rate on property and the poll tax. The requirement of payment of poll tax as a prerequisite for voting was abolished. Revaluation was accomplished in 1920 and the property in the state was assessed at $3,539,000,000. More than a million ac. of land not hitherto on the tax books were included. The *per capita* taxable wealth was increased 183%. The amendments were ratified by large majorities and the state seemingly assured of equitable taxation, but a reaction became strongly manifest in the Legislature of 1921 endangering the results of revaluation.

*Education.*—The state made creditable educational progress between 1910 and 1920. The public school funds increased from approximately $3,000,000 in 1910 to $15,066,487 in 1920. A consti-

tutional amendment ratified in 1916 increased the minimum school term from four to six months. Teachers' salaries showed an upward tendency at the close of 1920, and steps were being taken to secure better equipped teachers. The most notable educational achievement was the rapid growth of a state high-school system. In the case of the state institutions of higher learning, appropriations for maintenance and permanent physical improvements increased largely, and their growth was steady. The sectarian schools and colleges were also more adequately supported and showed a similar growth. The state support of its benevolent and charitable institutions became increasingly generous and several new ones were established in the decade, including the Caswell Training School at Kinston for the mentally defective, an institution for fallen women at Samarcand, a tuberculosis sanitorium at Sanitorium, a Confederate women's home at Fayetteville, and an orthopaedic hospital at Gastonia.

*History.*—The state Government throughout the period 1909–21 was under the undisputed control of the Democratic party. In 1913 Locke Craig succeeded William W. Kitchin as governor, and in 1917 was succeeded by Thomas Walter Bickett. In 1920 Cameron Morrison was elected governor. The Legislature at every session had large Democratic majorities. One Republican member of Congress was elected in 1914. So confirmed was the Democratic faith of the people of the state that alone of all the states it increased the party majority in the election of 1920. There was little of purely political interest during these years. The striking fact was the influence exerted upon politics by the steady development in the state of a social consciousness which manifested itself in demands for advanced social legislation. The result was a greater body of progressive legislation than that of any other southern state for the same period. During the World War the state furnished to the armed forces of the nation 88,168 men; casualties were 1,610 killed and 4,128 wounded. The subscription to Liberty and Victory loans was $138,095,400, besides $21,085,388 for war stamps. (J. G. DE R. H.)

**NORTHCLIFFE, ALFRED CHARLES WILLIAM HARMSWORTH,** 1ST VISCT. (1865– ), British newspaper proprietor and statesman, was born July 15 1865 at Chapelizod, Dublin, the eldest of a family of fourteen. His father, Alfred Harmsworth (1837–1889), descended from an old Hampshire family, was a barrister-at-law of the Middle Temple and one of the standing counsel for the Great Northern Railway Company. His mother, Geraldine Mary (b. Dec. 24 1838), a woman of remarkable intellect and strong character, was a daughter of William Maffett, well known in Ireland in his time as a banker and land-agent, of Ulster-Scottish descent. Of the seven sons, the two eldest, Alfred and Harold, became members of the House of Lords as Lord Northcliffe and Lord Rothermere respectively; the third, Cecil Bisshopp (b. 1869), became in 1915 Under-Secretary for Home Affairs and in 1919 Under-Secretary for Foreign Affairs, having entered the House of Commons as Liberal M.P. for Droitwich (1906–10) and subsequently sitting for S. Beds. (from 1911); while the fourth, Robert Leicester (b. 1870), who was created a baronet in 1918, entered the House of Commons in 1900 as Liberal M.P. for Caithness, a seat which he still retained in 1921. The other three sons were Hildebrand Aubrey (b 1872), from 1901 to 1904 editor of the *New Liberal Review;* St. John (b. 1876), the creator of the "Perrier" mineral-water business; and Vyvyan George (b. 1881).

It was in 1867 that the Harmsworths moved to London, and the family means were then small. Alfred, the eldest child, was exceptionally energetic, studious and thoughtful. At 11 he went to Stamford grammar school and at 13 to Henley House school, West Hampstead, where in 1878 he started the first of his journalistic adventures, a school magazine. This was originally issued in MS. but was afterwards printed and sometimes set up by himself in his spare time. At 15 he did some work for Mr. Jealous, then editor of the *Hampstead and Highgate Express*, from whom he received his first very modest payment in journalism. In 1881 he began to work under a tutor for Cambridge, while contributing as a "free-lance" writer to the *Bicycling News*, *Globe* and the publications issued by James Henderson for boys and girls, in one of which Stevenson's *Treasure Island* made its first appearance. As secretary and companion to one of the third Lord Lilford's sons, he travelled extensively in Europe. On his return to London Sir William Ingram (of the *Illustrated London News*) made him assistant editor of his paper *Youth* at the age of 17; and he continued "free-lance" work for the press, contributing leading articles to various newspapers, among which was the *Morning Post*, and articles to the *St. James's Gazette*, where his work attracted the attention and praise of Frederick Greenwood. But his health temporarily broke down in 1884. Ordered to live out of London, he went to Coventry in 1885 and worked for the firm of Iliffe & Sons, owners of many publications, including the *Midland Daily Telegraph*. With them he remained till 1886. He subsequently regarded his experience during this period at Coventry as specially valuable. He declined the offer of a partnership made him by Mr. Iliffe before he was 21; and having saved nearly £1,000 went back to London, where he joined a general publishing business. This from the first had a promising existence. Among other ventures he started on June 16 1888 *Answers to Correspondents*, a weekly periodical intended to be a more popular form of *Notes and Queries*. Ere long it turned the corner and, as *Answers*, laid the foundation of what eventually became the largest periodical publishing business in the world, the Amalgamated Press. In 1889 larger offices had to be acquired. Alfred Harmsworth had already been joined by his second brother, Harold (*see* ROTHERMERE, LORD), to whom he ascribed a great share of the success of the undertaking, particularly on the business side. He himself wrote much, outlined serials, trained young editors, discovered new writers and artists, and revolutionized the current methods of periodical journalism. The profits of the accumulated publications soon soared to £50,000 a year. In 1892 he published the first "net sales" certificate, showing that the actual sales of the various Harmsworth periodicals were over a million copies a week; and in that year Mr. Gladstone praised *Answers* for its "healthy and instructive reading." In the next few years Alfred Harmsworth travelled much in Europe, India, Africa, Canada and the United States; he was a good athlete, excelling in lawn tennis, and in the days before the motor-car, which as far back as 1894 became one of his chief interests, was a great lover of horses, fond of cycling, and devoted to fishing. On April 11 1888, he had married Mary Elizabeth, daughter of Robert Milner, a West Indian merchant, and to her sure judgment and quick brain he always attributed much of his subsequent success.

On Aug. 31 1894 he and his brother Harold acquired the London *Evening News*, in which the Conservative party had sunk some £300,000. It was then losing money heavily, but it was at once reorganized by himself, his brother, Mr. Kennedy Jones and Mr. W. J. Evans, with such effect that the first working week yielded a profit of £7, and the first year one of £14,000. In the same year he fitted out an Arctic expedition under Mr. F. G. Jackson, which explored Franz Josef Land and assisted in the rescue of Nansen. In the general election of 1895 he stood unsuccessfully as a Conservative candidate for Parliament at Portsmouth. On May 4 1896 a new halfpenny morning paper, the *Daily Mail*, was launched, "the busy man's newspaper," as he called it. It embodied many innovations, a very full service of cables, the employment of numerous famous writers, condensation of unimportant topics, and costly and daring enterprises of various kinds. A comparison of past files of the London press shows how it revolutionized daily journalism. The most rapid machinery was used to the utmost; a system of arrangement was introduced which enabled the reader to know where to find the news he wanted. It was characteristic of the foresight which, with initiative, courage and tenacity, was among the secrets of its chief proprietor's success that one of the three leading articles in the first number dealt with the then almost unknown motor-car, in the future of which Alfred Harmsworth had a firm belief, being himself already a qualified driver. The *Daily Mail* rapidly attained an enormous sale, rising to 600,000 copies a day in the Boer War, and this gave him great influence on policy at home and abroad. In 1903 he founded the *Daily Mirror;* it was at first a complete failure, losing £1,500 a week, but after being soon transformed from a penny paper for women into a halfpenny illustrated morning journal, became as signal a

success. In 1905 a Continental edition of the *Daily Mail* was established, with headquarters in France. In the same year Alfred Harmsworth was created a baronet, and in 1905 he was raised to the peerage as Baron Northcliffe. In 1906 he and his brothers acquired for their companies about 3,000 sq. m. of forest land in Newfoundland, with lakes, rivers and water transport, for the manufacture of paper and wood-pulp, the result being the formation of the Newfoundland Development Co., a gigantic enterprise with its works at Grand Falls—where 23,000 H.P. turbines produce large quantities of mechanical pulp and 200 tons of paper daily—two lines of railway, a port, and Atlantic and other steamers.

In 1908 Lord Northcliffe obtained control of *The Times*, to own which had always been one of the aims of his life. New machinery was installed, and the size of the paper greatly increased; in March 1914 he reduced the price to one penny, with the result of a large increase in circulation, though the enormous rise of 600% in the cost of paper during the World War forced a return to the old price of threepence. Meanwhile Lord Northcliffe had acquired the *Weekly Dispatch;* disposed of the Sunday *Observer*, which he for some time owned; and sold the *Daily Mirror* to his brother, Lord Rothermere; so that at the outbreak of the war "the Northcliffe Press," so widely mentioned and abused by contemporaries, consisted of *The Times; The Times Weekly Edition; Daily Mail; Overseas Mail; Evening News* and *Weekly Dispatch.*

Among the reforms which Lord Northcliffe introduced into newspaper management were the five-day week for editors, sub-editors and reporters, a more generous payment of journalists and a system of profit-sharing by the chief members of his staffs.

From 1900 onwards, through his newspapers, he had exercised an ever-increasing influence on politics. He had at one time been anxious, like Edward VII. and Cecil Rhodes, to obtain a friendly understanding between England and Germany, but the Boer War caused him to abandon that idea as impracticable. His newspapers consistently pleaded the cause of a strong navy, and as consistently warned the nation for 20 years of the peril from Germany. From 1902 he sought to effect an entente with France, and also to promote agreements with Russia and the United States, whose sentiments and prejudices he had learnt in many visits. He opposed in 1911 the Declaration of London—a code of sea law which most naval officers condemned as "made in Germany"—and finally assisted in securing its rejection. This rejection enabled the British fleet to blockade with effect in the war. Through the *Daily Mail* he gave large prizes for airmanship, in which, from 1906 onwards, he took the warmest interest; the offer of a prize of £10,000 in 1906 for the first aeroplane flight from London to Manchester was received in some quarters with a good deal of derision, which vanished, however, when in 1910 the prize was won. His maiden speech in the House of Lords was devoted to the pressing claims of aircraft. He was a strong believer in the future of flying and a daily advocate of the value of aircraft in war. He was also interested from the first in submarines, in one of which craft he made an early and hazardous descent. For many years he was a strong supporter of his friend, Lord Roberts, in the campaign for national service.

In the World War he took the lead in advocating almost every measure of reform that was carried through in Great Britain, usually weeks or months before it was introduced. He was indeed described by Mr. L. J. Maxse as "the great driving force in our country during the war" (*National Review*, July 1917). He aimed at the most vigorous possible conduct of the struggle, and was from the first of opinion that the war would be long and desperately contested. The chief newspaper campaigns which he carried out, always with the aims of victory and close union between the Allies, were: (1) for the removal of Lord Haldane from the War Office in Aug. 1914; (2) for the organization of the munition supply and provision of high-explosive shells in April and May 1915, when he did not hesitate to lay the responsibility for the shortage of ammunition on Lord Kitchener in leading articles written by himself in the *Daily Mail* of May 19 and 21, the second of which was publicly burned on the London and other stock exchanges; (3) this campaign was one of the causes of the formation of the Coalition Ministry by Mr. Asquith; (4) throughout 1915 and early 1916, in the teeth of storms of abuse, he urged the necessity of introducing compulsory service as the sole means of winning the war; (5) he protested continuously against the excessive optimism of Mr. Asquith's Government and of its press supporters, and against the whole system of official secretiveness by which grave failure was concealed; (6) he called for the strict enforcement of the blockade and the stoppage of the supplies which were reaching Germany through neutral countries; (7) he pointed out the impossibility of conducting a successful war with a debating society of 23 or 24 persons, such as formed the Cabinet; (8) so far as the censorship would allow, he resisted the "side-shows," such as the Dardanelles and Salonika campaigns, which absorbed so large a part of the national forces; (9) he continued his pre-war demand for the construction of aircraft and "the right kind of aircraft"—on the largest possible scale, and he called for effective measures against Zeppelins and for warnings in the case of imminent air-attacks; (10) he urged the necessity of creating a strong naval war staff and taking offensive measures against the enemy submarines; (11) he insisted on the need for a system of compulsory food rationing.

While always active with his pen and through his press, he went repeatedly to the various battle-fronts, British, French, Belgian, Italian and American, and kept in close touch with the various staffs. Thus in 1916, at the crisis of the battle of Verdun, he visited Verdun (March 4), conferred with Gen. Pétain, watched the struggle, and the same night motored back to Paris and wrote a long dispatch which was reproduced in whole or part by 3,000 Allied or neutral newspapers, giving the welcome and unexpected news that Verdun was "unlikely to be taken." He paid other visits—to Spain, whence he sent warning of the activity of the German propaganda, and to Switzerland, where he investigated the condition of the British interned prisoners. With his daily assistance, Sir R. Hudson raised through *The Times* fund a sum of approximately £21,000,000 for the British Red Cross, while Lady Northcliffe (who in 1918 was created G.B.E.) maintained a private hospital and took a prominent part in the control of Red Cross finance and operations. So wide was Lord Northcliffe's influence and so greatly feared by the Germans that they published a special periodical, the *Anti-Northcliffe Mail*, devoted entirely to clumsy attacks upon him as the chief Allied energizer in the war. In 1916 they issued their bronze "hate" medal of him. There is reason to believe that when Broadstairs was shelled on Feb. 24 1917, and Elmwood, his own house (where he was then staying), was hit, and three near-by deaths occurred, he was intentionally one of the targets of this German destroyer attack. In Dec. 1916 he gave his support to Mr. Lloyd George in the political crisis which led to the fall of Mr. Asquith's Government, and dealt the final thrust which brought that Government down, though after the Armistice, by reason of his objection to the long-drawn-out after-war negotiations with the Germans, he became Mr. Lloyd George's most persistent critic. He was offered office but declined, believing that it was his duty to keep his hands free and hold the Government up to the mark. He did, however, because the office was strictly non-political, accept the chairmanship of the Civil Aerial Transport Committee, on the establishment of that body in 1917.

Before the United States entered the war he was offered and declined the post of British ambassador at Washington. He received, however, an urgent call to go to the United States on May 30 1917. The War Cabinet had greatly desired him, after conference with leading Americans, to go to the United States as chairman of the much-needed British War Mission. He accepted this appointment, though with some reluctance. After an audience with the King, he left England on June 2, arriving in New York on June 11, with the understanding that he should not remain more than three months. During the next few months he coördinated the work of the numerous British departmental missions; controlled an expenditure of £10,000,000 to £15,000,000 a week; maintained the closest and most friendly relations with President Wilson and the American Government; and in a series

of speeches and visits to the Middle West and eastern Canada he set forth the work that had yet to be done if the war was to be won, and the immensity of the British effort. Having prolonged his stay far beyond the original three months, he returned to London on Nov. 12 1917, when he was created a viscount, as Visct. Northcliffe of St. Peter-in-Thanet, for his services.

In a letter dated Nov. 15 1917 he declined Mr. Lloyd George's offer of the post of Air Minister, on the ground that he was indisposed to enter an administration with the energy of which he was by no means satisfied. But on Feb. 13 1918, on the distinct understanding that he was to remain free to criticise and suggest, he accepted the office of Director of Propaganda in Enemy Countries. To pave the way for operations among the nationalities subject to the Habsburgs, he secured an agreement between the Yugoslavs and the Italian Government, which played an important part in the defeat of the Austrian army and was subsequently embodied, in substance, in the peace terms. The evidence of numerous German generals, statesmen and writers is that the skilful direction of his propaganda against Germany destroyed confidence in the German people and weakened the German army on the eve of its last offensive (July 15 1918), when it seemed on the verge of decisive success. Gen. Ludendorff himself says: "Lloyd George knew what he was doing when, after the close of the war, he gave Lord Northcliffe the thanks of England for the propaganda which he had carried out. Lord Northcliffe was a master of mass-suggestion." The deadliness of his propaganda lay in its veracity—in emphasizing such facts as the rapid movement of United States troops to Europe, the failure of the U-boat campaign and, when the Allied victories began, the enormous captures of guns and prisoners. An account of this work was given in Sir Campbell Stuart's *Secrets of Crewe House* (1920).

At the Armistice Lord Northcliffe was ill, suffering from an adenoma of the thyroid gland, for which, in June 1919, he underwent a serious operation, and it was only after some months that he gradually made a complete recovery. During the Peace Conference his press and the *Continental Daily Mail* in particular exerted a powerful influence on the British Government, extracting from Mr. Lloyd George a promise to fulfil his election pledges and striving to maintain the closest and most cordial relations with France.[1] In July 1921 he went for a prolonged tour of the world.

In golf and motoring Lord Northcliffe found his main relaxations in later life, and he remained a keen and skilful fly-fisherman and salmon-angler. He was the author of volumes in the Badminton series on *Motoring* and *Tarpon Fishing*, and he also published a collection of letters, telegrams and accounts of his visits to the various fronts (*At the War*, 1916), of which 60,000 copies were sold. Simple and direct in style, his own writing was always marked by pugnacity and humour. His Verdun despatch has indeed been praised as a model for war correspondents, and throughout his newspaper organizations he was accustomed to insist on economy of words and the employment of straightforward Anglo-Saxon diction. It was his regular practice to issue the frankest reports on his various papers to their staffs, abundantly illustrating the far-reaching character of his initiative in suggestion, severity in criticism and warmth of appreciation.

(H. W. W.)

**NORTH DAKOTA** (*see* 19.779) had in 1920 a pop. of 645,680, as compared with 577,056 in 1910 and 319,146 in 1900, an increase in the latter decade of 68,624 or 11·9%; in the earlier of 257,910 or 80·8%. The state remains essentially rural, as is indicated by the following table giving the pop. of the chief cities in 1920 and 1910, and the percentage of growth.

| | Pop. 1920 | Pop. 1910 | Increase Per cent |
|---|---|---|---|
| Fargo | 21,961 | 14,331 | 53·2 |
| Grand Forks | 14,010 | 12,478 | 12·3 |
| Minot | 10,476 | 6,188 | 69·3 |
| Bismarck | 7,122 | 5,443 | 30·8 |
| Jamestown | 6,627 | 4,358 | 52·1 |
| Devils Lake | 5,140 | 5,157 | 0·3* |
| Valley City | 4,862 | 4,606 | ·05 |
| Mandan | 4,336 | 3,873 | 11·9 |
| Williston | 4,178 | 3,124 | 33·8 |
| Dickinson | 4,122 | 3,678 | 12·08 |

*Decrease.

*Agriculture and Industries.*—The following table shows agricultural and industrial conditions:—

| | 1920 (estimated) | 1910 |
|---|---|---|
| Total farm acreage | 30,000,000 | 28,426,650 |
| Value of farm property | $1,810,876,000 | $974,814,205 |
| Total value of all crops | $ 192,248,000 | $180,630,520 |
| Wheat, bus. | 68,400,000 | 116,781,886 |
| Oats, bus. | 59,640,000 | 65,886,702 |
| Barley, bus. | 22,680,000 | 26,365,758 |
| Rye, bus. | 9,340,000 | 689,233 |
| Corn, bus. | 17,064,000 | 4,941,152 |
| Flax, bus. | 3,896,000 | 10,245,684 |
| Potatoes, bus. | 7,110,000 | 5,551,430 |
| Hay and forage, tons | 2,946,000 | 3,010,401 |
| | Jan. 1 1921 | 1910 |
| Value of live stock on farms | $99,876,000 | $106,761,317 |
| Horses | 49,600,000 | 83,461,739 |
| Cattle | 42,251,000 | 17,711,398 |
| Swine | 5,628,000 | 3,152,909 |
| Mules | 765,000 | 1,149,001 |
| Sheep | 1,632,000 | 1,257,737 |
| Dairy products | 30,000,000 | 4,872,304 |
| Mill products | 25,600,000 | 11,685,116 (1909) |
| Mine products | 2,166,168 | 564,812 (1909) |
| No. of mine employees | 1,268 | 903 |
| No. of operators of mines | 136 | 53 |
| No. of acres irrigated | 12,000 | 10,248 (1909) |
| Cost per acre[1] | $2.50 | $38.17 |

[1] In 1920 this cost was for operation only; in 1910 it included the outlay for experiments and installation.

*Education.*—A state normal school was opened at Minot in 1913 and another at Dickinson in 1918. The number of children of school age in 1920 was 204,887; the number enrolled in public schools in 1919 was 162,358; the average daily attendance, 156,495. The state appropriations for rural schools for the biennium 1909–11 were $225,000 and for the biennium 1919–21 $425,000.

*Finance.*—A state budget system, effective in 1915, created a budget board with the duty of preparing a biennial statement of all state needs for the Legislature. This board consists of the governor, treasurer and auditor, and the chairmen of the appropriations committees of the Senate and House. In 1919 a single tax commissioner replaced a board of three members. Important changes in taxation were the exemption of farm improvements, the reclassification of property for assessment and the enactment of a classified and graduated income tax. The state bonded debt July 1 1920 was $2,442,300. The receipts for the biennium ending June 30 1919 were $7,958,439 and the expenditures $6,499,849. For 1920 the income tax yielded approximately $550,000. New sources for revenue created since 1911 are: the inheritance tax, capital stock tax, oil tax, income tax and motor-vehicle licence tax. The rate of levy for the state on the estimated true value of property in 1919 was in mills 1·07, and the *per capita* general property tax levy was $2.21. In 1920 22·7% of the state tax was for education.

*Government.*—A state Board of Administration was created in 1919, consisting of the superintendent of public instruction and the commissioner of agriculture and labour as *ex-officio* members and of three members appointed by the governor for six years. This board, exercising the functions formerly vested in the state Board of Control, administers the state educational, penal and charitable institutions. The state Supreme Court was by constitutional amendment increased to five members in 1908, and by a further amendment adopted in 1918 the power of the court to declare legislation unconstitutional was limited to cases in which four of the five judges concurred. In three of the six judicial districts there are three judges each and in three two judges each, all elected for four years. In 1914 by constitutional amendment the initiative and referendum were made applicable to all legislation and provision was made that a constitutional amendment could be initiated by popular vote. Further changes in the system of state government are described below.

*History.*—The political and social history of North Dakota during the period 1911–21 attracted a good deal of outside

[1] It may be noted that, shortly after President Wilson first arrived in Paris, Lord Northcliffe obtained from him a statement of his views, expressing *inter alia* a modification of his earlier attitude on the "freedom of the seas." Mr. C. H. Thompson, the American correspondent of the Associated Press, in his *Peace Conference Day by Day* (pp. 306–7), says that "this was one of those quiet but inestimable services which Lord Northcliffe rendered to his country and to the Prime Minister, who at that time was his close friend."

attention. Serious abuses in grain grading and marketing had been pointed out by the State Bankers' Association as far back as 1906. The Legislatures in 1909 and 1911 passed an amendment to the constitution, ratified by popular vote in 1912, which made it legal to provide for a state-owned terminal grain elevator. A second amendment for a terminal elevator within the state became effective in 1914. The Legislature of 1913 laid a tax to create a fund to build a terminal elevator and the Board of Control was authorized to prepare plans. In 1915 the Board reported against the whole plan, the tax was repealed and no appropriation made.

In the spring of 1915 a movement was begun to organize the farmers politically upon the following platform: (1) state ownership of terminal elevators, flour-mills, packing-houses and cold-storage plants; (2) state inspection of grain and grain dockage; (3) exemption of farm improvements from taxation; (4) state hail insurance on an acreage basis; (5) rural credit banks operated at cost. The movement was so successful that by Nov. 26,000 members had joined the Non-Partisan League.

The first state convention was held at Fargo March 28 1916, and a full state ticket was nominated. At the primary election in June all the nominees supporting the League were elected, with the exception of the state treasurer. The Legislature was divided; the House was controlled by the supporters of the League, the Senate by its opponents.

The 1917 Legislature provided for: (1) state grain grading; (2) Torrens title registration; (3) state guarantee of deposits in state banks; (4) reduction of assessments on farm improvements to 5%; (5) a state highway commission; (6) a tripling of the former appropriation for rural schools.

After the United States entered the World War the state prepared to take its part and a special session of the Legislature was called for Jan. 1918. A Seed and Feed Loan Act was passed to relieve drought-stricken farmers in the western part of the state. Special county bonds could be issued under this law to provide funds, and possible conflict with the work of the Federal Land Banks was obviated by a special issue of state indemnity bonds to protect Federal loans to farmers. A moratorium was laid on all debts of men in the national service and a State Council of Defence created.

The adoption of a new industrial programme by the farmers of the state in 1918 was not the result of any sudden impulse or mere theory. The investigations of the faculty of the state Agricultural College supplied the foundation for the new system of grain marketing. For instance, President E. F. Ladd of the college gave scientific proof of the loss of fertility that followed the constant shipping of grain out of the state. The annual loss to the soil he estimated at 46,018,440 lb. of nitrogen; 44,648,760 lb. of phosphoric acid; 10,700,200 lb. of potash and 1,787,280 lb. of lime. He showed, also, by experiments in the model flour-mill at the college that the grain grades of the Minneapolis Chamber of Commerce were not based on the flour-producing quality of the various crops handled by them, but were arbitrary, and that they tended to deprive the farmer of any possibility of raising grain at a profit. The methods used by the wheat buyers and millers at Minneapolis, St. Paul and Duluth had been carefully studied by the same investigators and their conclusions were well known throughout the state.

On this solid foundation of research and practical experience was built the programme of legislation carried through after the election of 1918.

At the same election several important amendments to the state constitution were ratified. The first subject dealt with in these amendments was the power of the people to pass on or to initiate legislation and a similar power to propose and adopt constitutional amendments without the action of the state Legislature. The specific provisions in these amendments require the signatures of 10,000 voters to a petition calling for a referendum on any law. A majority vote at an election is required to pass or repeal a law so initiated or referred. An amendment to the constitution may be proposed by a petition signed by 20,000 voters, and if approved by a majority of the votes cast on the measure at the special election, it becomes a part of the constitution. The second subject dealt with was the power of the state or of a municipality to engage in any industry or business. The third subject was the debt limit of the state, at that time $200,000; the amendment authorized the state to borrow up to $2,000,000 on state bonds, all above that amount to be secured by first mortgages on real estate at not more than one-half its value or upon the full value of state-owned utilities or industries. If state-owned public utilities or industries are offered as security for bond issues, the amount of the issue must not exceed $10,000,000. Other amendments gave the Legislature power to exempt from taxation all personal property and to levy an acreage tax on farm-land to provide funds for a state system of hail insurance. These amendments were adopted at the elections in Nov. 1918 by an average vote of over 48,000, and opposed by a vote of about 32,000. At the same elections the Non-Partisan League obtained control of both Houses of the Legislature and elected their candidates for all but one of the state offices.

With the whole machinery of the state in the farmers' hands, their legislative programme was enacted into law at the following session. There was created an Industrial Commission, consisting of the governor, the attorney-general and the commissioner of agriculture and labour, which was given power: (1) to manage, operate and control all state-owned utilities, industries and business projects created by law; (2) to purchase or lease sites for these industries; (3) to sell all such property and to fix prices of all products of these industries; (4) to provide funds by the sale of bonds for the carrying-on of the state-owned industries and other business undertakings.

There was also created a Mill and Elevator Association placed under the Industrial Commission. In Aug. 1919 a small mill and elevator were purchased at Drake, in McHenry county, on the Soo railway. In Nov. 1919 Grand Forks was chosen as the site of the projected three-unit mill and elevator and in the following spring construction began. The structure was planned to cost approximately $1,500,000, with a daily producing capacity of 3,000 bar. of flour, and a storage capacity of 1,659,500 bus. of grain and 70 car-loads of flour. The annual grinding capacity of the mill was to be 900,000 bar. of flour, which would fully supply home consumption. The production of a corresponding amount of mill-feed for live stock was to be one of the most important results of the new project, since it would tend to overcome the loss of fertility which always overtakes a producing area that rests its prosperity upon a single crop manufactured and consumed elsewhere. The grain-grading law marks the culmination of a long struggle on the part of the farmers to secure fair grading of grain. It provides that elevators buying grain in North Dakota shall grade it rather according to its milling and baking value than according to its physical characteristics. It has been estimated by experts of the North Dakota Agricultural College that this law should save growers in the state about $11,000,000 annually.

Another state institution vitally connected with the industrial programme of 1919 is the state Bank of North Dakota, which began business July 28 1919 as an institution founded, owned and controlled by the state. It is the legal depository of all state bonds issued for the purposes of all the business enterprises under control of the Industrial Commission. It was originally the legal depository of the funds of all local governments such as cities, counties and school districts, but this provision was repealed by an initiated law adopted at the state election in Nov. 1920. The bank pays from 2 to 3% interest on the checking accounts of all public funds and from 4 to 6% on time deposits, but these rates are subject to change. The public funds are redeposited in the banks of the state with special reference to local needs.

Up to 1921 the bank had not been opened to private depositors but early in that year the policy was changed so as to make the bank a general bank of deposit, with branches to be established throughout the state as needed to carry on this phase of its work. It is authorized to loan on first mortgages on real estate in North Dakota up to one-half value of the security, providing funds for the purpose by the sale of real-estate mortgage bonds. Loans are also authorized on warehouse receipts issued by the Industrial Commission or by any licensed state warehouse up to 90% of the value of the property covered. The amount of the real-estate loans is limited to 30% of the bank's capital and 20% of its deposits. The loans require payment of fixed annual instalments. In 1921 these annual instalments were 7% of the loan principal, 6% for interest and 1% for principal. The unpaid balance is added to the 20th instalment of interest and principal in liquidation of the loan. The state guarantees all deposits of this bank and also all bonds that are handled for the state. The average rate of interest in the state is fixed by the operation of the state bank as a loan agency at 6% or at 6·25% plus commission, while the previous average rate in 1916 was 8·7% on farm mortgages, plus commission.

The laws providing for the Industrial Commission and for the Bank of North Dakota were carried at a referendum election in June 1919 by an average vote of over 61,000 against a little over 49,000. The constitutionality of the laws was tested by two suits, appealed to the U.S. Supreme Court. The decision of this court, given June 1 1920, upheld the lower courts in declaring the laws constitutional. In its decision the court said: "Under the peculiar conditions existing in North Dakota, which are emphasized in the opinion of its highest court, if the state sees fit to enter upon such enterprises as are here involved, with the sanction of its constitu-

tion, its legislature and its people, we are not prepared to say that it is within the authority of this court, in enforcing the Fourteenth Amendment, to set aside such action by judicial decision."

The Industrial Commission is responsible also for the Home Building Association. The funds for the project came from the sale of state bonds and the deposits made by those desiring to invest in homes. Any individual or organization may deposit with the state 20% of the cost of constructing a home and the state undertakes to build it and turn it over to the investor in full ownership, securing the balance by a mortgage calling for annual payments through a period not exceeding 20 years. The cost of a town home may not exceed $5,000 and the limit of $10,000 is placed on the cost of a farm home, including the usual accompanying buildings. The Hail Insurance Department created by law in 1919 insured in 1920 over 12,000,000 ac. of farm-land at an average rate of $.28, effecting a very large saving for the farmers. At the special session of 1919 a Dairy Association law was passed, authorizing counties to issue bonds for the purchase of dairy cows to be sold to farmers, in order to utilize the extensive areas in the state not fitted for crops.

One of the most interesting features of the farmers' programme is the alliance established with organized labour. The state enacted in 1919 a law establishing a Workmen's Compensation Bureau, consisting of the commissioner of agriculture and labour and the commissioner of insurance *ex officio* and three members appointed by the governor representing respectively labour, the employer and the public. It is based upon the Iowa law, and of all such laws now in force in 42 states of the Union is the most liberal in its provisions for compensation and the number of classes of employees included. The funds are derived from annual payments by the employer, the rates being graded according to the hazards of the employment. The Act provides completely for all injuries received in the course of employment. In the intent of the Act is included the restoration to industry of those injured and this purpose is to be secured by coöperation with the Federal Board of Vocational Education. Under the minimum-wage law the bureau has held hearings in various parts of the state and has fixed the minimum wage of women and minors as well as proper conditions of employment. Other labour legislation passed includes: (1) a complete coal-mining code; (2) a full-crew law; (3) an eight-hour day for women; (4) limitation of the use of injunctions in labour disputes; (5) authority to the Board of Railway Commissioners to compel all public utilities to furnish, provide and maintain all service, instrumentalities, equipment and facilities so as to promote the safety, health and comfort and convenience of its patrons, employees and the public.

During 1920 and the early months of 1921 45 state banks in North Dakota failed, of which one had reopened before May 1 and 10 more were then expected to reopen. The capital of these banks aggregated $960,000, an average of a little over $21,000 each; their loans and discounts totalled $9,425,543, their bills payable $2,150,464. It is apparent that these bank failures were due chiefly to successive crop losses and the heavy slump in 1920 farm prices, with consequent inability of the banks to collect their loans. This conclusion is borne out by the fact that banks in the Southern states showed the same relative number of closings, due to the drop in prices of staple farm products there. Another factor contributing to the financial stringency in North Dakota was the smaller volume of rediscounts from the Federal Reserve Bank, as compared with accommodations to other sections of the same district. Statements issued by the Federal Reserve Bank of Minneapolis show that rediscounts for member banks in North Dakota were relatively less than rediscounts in any other state of the Ninth District, whether on the basis of population or of production. The *per capita* figures were: Minnesota, $27; South Dakota, $18; Montana, $14; North Dakota, $8. Opinions differ as to whether this small ratio of rediscounts in North Dakota is to be ascribed to the failure of member banks in North Dakota adequately to take care of their patrons by presenting paper for rediscount; or to the relative absence of discountable loans, owing to the great shrinkage of values in North Dakota, on account of crop losses and reduced prices.

The recall election of Oct. 28 1921 resulted in the recall of the three Non-Partisan League officials who composed the Industrial Commission, the governor, the attorney-general and the commissioner of agriculture and labor.

At this election, also, the constitutional amendments and initiated laws which were proposed for the purpose of changing or overturning the programme of the Non-Partisan League were all defeated by substantial majorities.

*The World War.*—The total registration of the state was 160,392 men; of these 27,253 were called to service in the army or navy. The state sent two regiments overseas, the First and Second North Dakota Infantry, and these regiments were attached to the 41st Division. The Liberty Loan subscriptions totalled $65,476,000, or over $100 *per capita*. The increased crop acreage of 1918 was confined to the chief agricultural needs of the war period, wheat and rye. Wheat showed an unusually heavy increase of 11%, rye acreage showed an increase of 100% over the harvested acreage in 1917, notwithstanding the fact that slightly more than 10% of the acreage planted in the fall had been ploughed down in the spring of 1918. North Dakota led the United States in the season of 1918 in the harvested acreage of wheat, barley, rye and flax.

The state governors were: John Burke (Dem.), 1907–13; L. B. Hanna (Rep.), 1913–7; Lynn J. Frazier (Rep.), 1917–21; R. A. Nestos (Rep.), 1921– . (O. G. L.)

**NORTHUMBERLAND, HENRY GEORGE PERCY, 7TH DUKE OF** (1846–1918), British politician, was born May 29 1846, and succeeded his father in 1899. He sat in the House of Commons as Conservative member for northern Northumberland from 1868 to 1885. He was treasurer of the Royal Household from 1874 to 1875, and as lord high steward bore the crown of St. Edward at the coronation of King George V. in 1911. The duke was known throughout life as an ardent Conservative and opponent of modern democratic ideas. He died at Alnwick May 14 1918.

His eldest son, HENRY ALGERNON GEORGE, EARL PERCY, of whose political career much was expected (*see* 19.788), died prematurely in Paris Dec. 30 1909; and on the 7th duke's death he was succeeded as 8th duke by his fourth but eldest surviving son, ALAN IAN, EARL PERCY, born April 17 1880. As one of the largest coal-owners in the north of England, he was summoned to appear as a witness before the Sankey Coal Commission (1919), and came much into public notice owing to his prolonged controversy with Mr. Robert Smillie, the leader of the miners, and subsequently to his anti-Communist campaign. He married in 1911 Lady Helen Magdalen Gordon-Lennox, youngest daughter of the Duke of Richmond and Gordon.

**NORTH-WEST TERRITORIES,** Canada (*see* 19.796).—In 1912 that part of the Canadian North-West Territories known as Ungava was incorporated in the province of Quebec and its name was changed to New Quebec. At the same time that part of Keewatin S. of 60° N. Lat. was divided between the provinces of Ontario and Manitoba. The North-West Territories now consist of the provisional districts of Keewatin (N. of 60° N. Lat.), Franklin and Mackenzie, and include that part of Canada which is N. of the 60th parallel, N. Lat., and between the Hudson Bay on the E. and Yukon on the W., including the islands in James Bay, Hudson Bay, Hudson Straits and other northern waters.

The territories are administered by a chief executive officer called the Commissioner of the North-West Territories, assisted by a council of four, all appointed by the Governor in Council of Canada, and for purposes of administration a separate branch of the Department of the Interior, whose minister advises the Crown, has been formed. Law and order throughout this immense extent of country are enforced by members of the Royal Northwest Mounted Police.

Special interest now attaches to the whole of these territories owing to the discovery of oil at Fort William and the existence of minerals throughout most of their area; also because of the experiments in breeding reindeer and the musk ox for economic purposes. They cover an area of approximately 1,250,000 sq.m. of which about 35,000 sq.m. are of water. The Mackenzie district has a total area of about 525,000 sq.m., the most noteworthy physical features being the Mackenzie river, 2,525 m. in length, including its tributaries, and the Great Bear and Great Slave lakes. The total area of the Mackenzie basin is 682,000 sq.m., the largest on the American continent next to that of the Mississippi. The Indian population in the southern portion is classified by Father Morice as Dene, sometimes called Chippewyans, and in the northern portion Eskimos. The climate is Arctic in its characteristics, severe in winter, and during the short summer the temperature occasionally reaches 90° F. and sometimes exceeds it. The western portion is much milder than the eastern. Continuous daylight is experienced for three months in most parts of the three districts, and N. of the Arctic circle the "midnight sun" is a feature of note. Agricultural possibilities are limited to the Mackenzie district. The large amount of sunshine gives a rapid growing season, enabling vegetables, grains and grasses to reach maturity in a remarkably short time. At Fort Smith, Resolution, Hay River, Providence and Simpson wheat, oats and barley, wild and domestic grasses and vegetables of nearly every variety common to western Canada have been successfully grown for over 50 years. Native flora is characteristically Arctic. Trees grow small and ill-formed, although there is a

uniform mantle of forest in the western part. Sedges abound covering a larger area than grasses; mustards are abundant and saxifrages plentiful. Mosses and lichens occur everywhere. The animals are chiefly fur-bearing. There are large herds of musk ox, now to be bred and used commercially for the meat market, and vast flocks of wild ducks, geese and other migratory birds spend summer in these northern wilds.

Two routes lead into the Mackenzie district, the one from McMurray, to which a railway has been constructed, via the Athabasca, Slave and Mackenzie rivers; the other from the Peace river via the Peace, Slave and Mackenzie rivers. River boats ply during the summer on the rivers and in winter travel is confined to dog trains. Ingress from the E. is via Hudson Bay and northern waters.

(W. L. G.)

**NORWAY** (*see* 19.799).—The population of Norway, according to the preliminary results of the census of Dec. 1 1920, had increased to 2,646,306, from 2,393,906 in 1910. Of the 1920 population, 1,863,300 (70·34%) were resident in the country districts and 785,700 (29·66%) in the towns. The urban population forms a constantly increasing percentage, a phenomenon which reflects the advancing industrialization of the country.

Emigration has always been greatest from the country districts and has deprived the land first and foremost of a large part of the peasantry's young manhood. During 1901–10 63% of the emigrants were males, and of these 72% were single. The incidence of emigration was greatest between the ages of 20 and 25 years, and next in the age-class of 15–20 and third 25–30. During 1910–20 emigration slightly but steadily decreased owing to the better opportunities of work at home, and the many hindrances to travel caused by the World War. The number of emigrants was as follows:—1911, 12,447; 1912, 9,105; 1913, 9,876; 1914, 8,522; 1915, 4,572; 1916, 5,212; 1917, 2,518; and 1918, 1,226. The greatest number of Norwegians emigrate to the United States, a few to Canada. The respective figures for these two countries are: 1911, 11,122 and 1,304; 1912, 7,776 and 1,287; 1913, 8,568 and 1,281; 1914, 7,723 and 775; 1915, 4,388 and 169; 1916, 4,865 and 320; 1917, 2,344 and 168; 1918, 1,179 and 30. It was estimated in 1921 that Norwegians outside the homeland numbered about 1,600,000, making a total of about 4,300,000 of Norwegians and descendants of Norwegians in Norway and America. The average yearly percentage of increase in the Norwegian population in 1900–10 was 0·66, and in 1910–20 was 1·02; for the country districts it was respectively 0·62 and 1·04, and for the towns 0·74 and 0·96.

Norwegians are, as a nation, of a comparatively pure race. Until the World War only two foreign races had domiciliary rights in the country, *i.e.* Lapps (or Finns) and Quains (*Kvaenerne*) or Finlanders. The first belong to the historical, ancient race of northernmost Norway, the last have immigrated from Finland during the last 200 years. The Lapps (speaking strictly, the Swedish description of folk who live in northern Norway are called "Finns") belong to the Mongolian race, and the Quains are derived from the scattered tribes of the population of Finland.

In 1910 18,590 Lapps were found in Norway, 0·79% of the whole population; and 7,712 Quains, 0·30% of the population. The majority of both these races live in the two northernmost provinces, Finmark and Tromsö, where their number, in comparison with the total population, is large. Of the 39,126 inhabitants of Finmark in 1910 (43,997 in 1920), 10,330 (26·4%) were Lapps, 5,398 Quains (13·8%). Of the population of Tromsö, 80,772 (90,637 in 1920), 6,279 (7·8%) were Lapps and 1,618 (2·0%) Quains. The figures of the proportions between the Norwegian and the immigrated population in 1920 were not available in 1921, but it can be said with certainty that they have not appreciably altered since 1910. Neither of these two small groups show any inclination to become fused with the Norwegian-born majority. As regards the Lapps there is even a movement in force to assert a separate national culture on the basis of the national tongue of the race and its own traditions by accentuating their ethnical solidarity and by defining the land boundaries of the Lapps. The Norwegian Lapps held meetings in 1920 and 1921 of representatives of their different tribes, at which they discussed common interests, and laid their claims before the Norwegian Government. They wished no longer to be called Lapps or Finns, but *Samer*, which they consider to be the original name of their race (*Suomi* being the Finnish name for the Republic of Finland). As the organ of their efforts towards emancipation they commenced the issue of a paper *Samelaisuus* ("the same people") at Vadsö in Sept. 1921. This propaganda for Lapp political aspirations, being hostile to Norway, could not be ignored, and has caused considerable unrest, particularly in northern Norway. In addition to Lapps and Quains, there were about 56,000 foreign-born residents in Norway in 1910, some of them of Norwegian descent. The number of foreigners was appreciably added to during the World War, principally by the entry of Russian and German fugitives, but also by French and English emigrants. The majority of these established themselves in Christiania and near by, and helped to increase the already too pressing house shortage. Not a few returned to their native country at the termination of the war.

According to the general census of Dec. 1 1920, the following towns had over 10,000 inhabitants:—Christiania, 260,920; Bergen, 91,081; Trondhjem, 54,520; Stavanger, 43,883; Drammen, 26,174; Haugesund, 16,563; Aalesund, 16,547; Christiansand, 16,543; Skien, 16,503; Fredrikstad, 15,579; Christiansund, 15,183; Tonsberg, 12,583; Larvik, 11,391; Fredrikshald, 11,218; Sarpsborg, 10,881; Horten, 10,413; Arendal, 10,358; Tromsö, 10,071. The boundaries of towns are fixed by law, and they do not always coincide with town-built areas. In addition to the actual towns there were many town-like rural centres which differed from the typical country community of a single farm, with its buildings occupied by a peasant with his family and servants. These areas with buildings are of a town type called "house collections" in the census, and in 1910 232,154 people, or nearly 10% of the total population, lived in such; towns and "house collections" together accounted for 39% of the population of Norway, while 61% lived scattered about the country, for the greater part in single farms and cottages.

Although 106 boys for every 100 girls are born in Norway yearly, women are in a greater majority than they were in most countries before the World War. In 1902 there were 1,076 women per 1,000 men, and this proportion has remained fairly constant. The reason for this ratio is to be found in the greater mortality and emigration of the men. The excess of women varies in different parts of the country; it is greatest in the towns, which have 1,206 women to 1,000 men, while in the country there are 1,058 women to every 1,000 men. Only in Finmark are there more men than women.

In Norway the oldest and youngest age-classes are the strongest numerically, while the age-class 15–40 is less than in most other countries. This is the result of emigration and of the high mortality in the middle age-classes of the male population. Of the 1920 population 35·4% were under 15 years, 35·8% between 15 and 39, 17·8% between 40 and 59, 11% 60 and over.

The average number of marriages contracted annually during the period 1911–15 was 15,320. During 1915 they were 15,940; (1916) 17,312; (1917) 18,086; (1918) 20,031; (Jan.–Sept. 1919) 15,608; (Oct. 1919–Sept. 1920) 18,032—or an average of 6·66 per 1,000 inhabitants yearly. The lowest marriage rate during this period was 6·10 in 1912 and the greatest (in 1918) was 7·77 per thousand. The number of divorces is increasing; while in 1896–1900 it was only 0·76 per 100 marriages, it was 3·32 in 1912, 3·28 in 1913, 2·69 in 1914, 3·52 in 1915, 2·06 in 1916, and 3·11 in 1917. In the later years somewhat over 60,000 children were born annually, representing a birth-rate of about 25 per 1,000. The birth-rate is comparatively low, and has been decreasing during the whole of the century. In 1896–1900 it was 30·44 per 1,000; the figure sank gradually to 23·42 in 1915, but increased a little during the following years, except in 1919 when it was only 22·47 per 1,000. About 7% (1896–1900 average 7·44%, 1911–19 average 6·93%) of the births were illegitimate.

Mortality has always been comparatively low in Norway, and in the long run its rate has fallen. The yearly deaths amounted to from 30,000 to 35,000. The yearly average death-rate per 1,000 inhabitants was: (1896–1900) 15·70, (1911–15) 13·34 (with the lowest figure in 1911, 12·98), (1916) 13·62, (1917) 13·35, (1918) 16·7—the great influenza epidemic,—(1919–20) 13·48. The Norwegian mortality rate for men varies from the general rule. It shows a falling mortality to 12 years of age, and thereafter a marked rise to 22 years; the rate then falls to 34 years and then again rises. While infant mortality (under 1 year) is lower in Norway than in any other European country and the mortality among the very young, and those over 50 years, is very low, the mortality between 20 and 30 years is higher than in any other country. The cause of this has not been determined, but tuberculosis is a strongly contributing factor. Mortality is higher in the towns than in the country, except among males of 17–25 years, and females 15–39, at which ages the country population has a higher rate of mortality than the town population. The total number of deaths in 1917 was 31,613. The principal causes of death, besides senile decay with 15·26% of all deaths, were pulmonary tuberculosis 13·47%, cancer and sarcoma 7·84%, apoplexy (apoplexia et embolia cerebri) 5·65%, organic heart disease 5·24%, inflammation of the lungs 5·17%, chronic bronchitis—catarrhal inflammation of the lungs 3·75%, and congenital debility 3·66%. In the terrible mortality year 1918, with 41,228 deaths, influenza was given as the cause of 7,248, 17·58% of all cases. Tuberculosis, which yearly carries off 2 per 1,000 of the population, prevails most seriously in Finmark, where the deaths from that disease in 1917 were 4·40 per 1,000; in Tromsö province the figure was 2·93, in Nordland 2·77; in North Trondelag 2·34, and in South Trondelag 2·34 per 1,000, while a high figure prevails in all the provinces of northern Norway. Energetic efforts to check this disease have been made by the Norwegian Anti-Tuberculosis Association, founded in Christiania on June 29 1910. On July 1 1920 this Association comprised, besides 2,287 life members, or industrial contributing members, 392 local

associations with a total membership of 78,500, and 535 town and district corporations. The National Association, which is under the patronage of the king and queen, receives a State subsidy (for 1900–21, 25,000 kroner). It publishes a quarterly journal, of which over 20,000 copies are issued. The secretariat is in Christiania. For the combat of tuberculosis the Norwegian Government has established five sanatoria—Reknes sanatorium at Molde, Landeskogen sanatorium in Setesdalen, Vensmoen sanatorium in Saltsal, and coast hospitals near Fredriksvaern (on the eastern side of Christiania Fjord) and in Vadsö (Finmark). The work against tuberculosis in the large towns has been much hindered by the shortage of housing accommodation. Official communications from the communal offices in Christiania alone in Sept. 1921 reveal the fact that 15,000 people were without accommodation. The poorer classes were crowded into rooms which were too confined; many had already been condemned as insanitary. The tuberculosis section of the Christiania Health Committee state in their report for 1921 that 40 % of the accommodation which had already been condemned as unfit for human habitation had again been put into use. Out of 381 newly reported tuberculosis families in 1920, 8·14 % lived in rooms without kitchens, 37 % in quarters of one room and kitchen, 35·43 % in two rooms and kitchen, and 11 % in three rooms and kitchen; only 18·64 % of this accommodation was found to be satisfactory from the point of view of health. Only 22·75 % of the sick had their own room, 77·25 % shared a room with others, up to 8 or 10 sick in the same room. A proposal for house rationing, which was rejected by the Christiania Town Council in 1919, therefore came to the front again in the autumn of 1921. Similar housing conditions existed in Bergen and Trondhjem.

*Railways.*—Norwegian railways underwent great development after 1910 when the plan adopted by the Storthing on July 9 1908 for the extension of the railways of the country was being carried out as far as the more important lines are concerned. The total length of railways in operation in July 1920 was 3,286 km. (2,041 m.). To this must be added the Dovre railway between Domaas in the northernmost part of Gudbrandsdal over the Dovrefjell to Trondhjem, opened for traffic on Sept. 19 1921, which has a length of 158 km. (98 m.) from Domaas south over Dovre to Storen station on the old Hamar–Trondhjem line. The total length of the Norwegian railways was therefore 3,444 km. (2,139 m.) late in 1921. Of the total rail length 2,290 km. (1,423 m.) are standard gauge (1·435 metres between rails); the remainder, exclusively branch-lines or small private railways, are narrow gauge, for the greater part with a gauge of 1·067 metres. Among the newest railways is the line between Kongsberg and Hjuksebö, opened February 11 1920, quite a short line (37 km. or 23 m.) but of great importance because it was the first section of the projected trunk-line through Norway's "Sørland" (southern part) between Christiania and Stavanger.

After the completion of the Bergen railway in 1909, no event in the railway field attracted greater attention than the opening of the new railway across Dovre. The trunk-line between Christiania and Bergen (492 km., 306 miles) constitutes Norway's main connexion with the outer world. The trunk-line (553 km., 343 m.) between Christiania, Eidsvoll and Domaas 214 m.; Domaas and Stören 98 m. and Stören and Trondhjem 32 m., constituted in 1921 the main connexion between South and North Norway. It was in fact the spine of the railway system, and no later line of importance can be constructed without having some reference to the Dovre railway. Its importance from an economic and military as well as from a traveller's point of view is obvious. In 1908 the cost was estimated at about 17,000,000 kroner (£944,000), and the final cost is estimated at 61,000,000 kroner. The Dovre railway was officially opened on Saturday Sept. 17 1921 by the king at Hjerkinn, the highest point of the line, 1,017 metres (3,334 ft.) above sea-level, and was marked by great celebrations at Trondhjem. On Sunday night, Sept. 18, when a special train left Trondhjem for Christiania a serious collision with the north-going express from Christiania took place not far from Trondhjem. Six persons, all men of prominence, were killed, and thirteen injured.

The Rauma railway starts from the southern terminus of the Domaas–Dovre railway and was under construction in 1921 between Romdal and Aandalsnes, a tourist centre at the outlet of the Rauma into Romsdals Ejord. It was intended to carry this railway westward to Aalesund. The Domaas–Björli section of this railway, the eastern half, was ready for working about the end of 1921. Domaas had already become an important junction. In the westlands districts, interest in the development of railway construction had increased considerably during 1920–1, and two railway committees were working in Bergen on the investigation of several plans. One of these relates to a connecting line between the Dovre railway and the Bergen line, and a probable solution inclines to the laying of a broad-gauge line of about 200 km. between Torpe station on the Bergen line (274 km. east of Bergen) and Kvam station 66 km. south of Domaas, the estimated time of construction being 10 years and the cost 36,000,000 kroner. This railway is not, however, included in the scheme worked out by one of the chief railway authorities for a construction period of 12 years (starting 1922) at a total cost of 273,000,000 kr. (£15,000,000). The railway authorities have also worked out a general scheme for the future development of the railways of the country at an estimated cost of 1,300,000,000 kroner. This scheme was to be brought before the Storthing in 1922. The Storthing had, however, in 1921 already approved the immediate commencement of work on the construction of the Sunnan–Grong section of the proposed great trunk-line, Norway's greatest railway project through Nordland. Up to July 1920 an invested capital of 412,120,000 kr. had been sunk in constructed railways. The interest-earning capacity of this capital has shown a falling tendency in recent years, and in the working-year 1917–8 the working expenses for the first time in the history of the railways of Norway were greater than the traffic receipts. The railways afterward worked with a deficiency which was for the period mentioned 7,550,000 kr., in 1918–9 2,510,000 kr., 1919–20 3,530,000 kroner. The reason for this deficiency is first and foremost the extraordinarily increased expenditure on wages, and secondly the high price of coal during and after the World War. Although all rates had been more than doubled, yet it had not been possible to cover expenditures. Freight increases finally brought strong protests from traders, and at the third Scandinavian Trades Meeting held in Christiania on Sept. 13–14 1921 the traffic question was one of the principal topics of discussion; an urgent appeal was made to the authorities concerned to look into the matter of traffic between the three Scandinavian countries as regards relief by reductions of charges and freights. The general director of the Norwegian State Railways immediately promised to comply with this appeal.

Work on the conversion of railways to electrical power was resumed, after having been practically stopped during the World War. The line between Christiania and Drammen, the first electrically operated railway in Norway, and the section from Christiania to Asker (23 km.) with heavy local traffic, was to be worked on this system from Jan. 1 1922.

*Roads.*—The Norwegian system of roads is being steadily expanded by new construction and by rebuilding. A thorough revision of highways legislation (which dated from 1851) was made by the Highways Law of June 21 1912, which came into force July 1 1913. Public roads are either high roads or parish roads. By high roads are understood (1) the more important highways which connect Norway with neighbouring states or provinces, (2) roads which, within a province, convey through traffic between two or more districts or form the principal means of access to towns. All other roads are considered as parish roads. The high roads are controlled by a Director of Highways for the whole country, who is directly under the Department of Public Works. In addition there is a provincial Direction of Roads for each province, consisting of the head of the province and two elected members of the provincial council. Norway's high roads in 1915 had a total length of 13,146 km. (8,165 m.), parish roads 20,139 km. (12,510 m.), a total of 33,285 km. (20,675 m.) of public driving roads. There were in 1921, on the average, 110 km. of such roads for every 1,000 sq. km. of the total land area of Norway.

Simultaneously with the Highways Law of 1912 a "Law for the use of Motor Vehicles" was passed, which opened all the roads and avenues of the country to automobiles. Including motorcycles, the total number of motor vehicles in Norway in Jan. 1921 was about 14,000, while 30,000 licences had been issued to motor drivers. About 270 motor routes have been opened up over the whole country and these play a big part both in general passenger and goods transport, as well as in tourist traffic. Among the most important routes which connect areas of the country where railways do not exist are the following:—Otta–Geiranger–Stryn–Domaas–Aandalsnes; Fagernaes–Tyin–Laerdal; Fagernaes–Bygdin; Gol–Laerdal; Dalen–Haukeli–Odda; Christiansand–Aaseral–Mandal; Christiansand–Arendal; Osebykle (Setesdalen)–Arendal–Evje; Kragerø–Tørdal; Notodden–Kviteseid; Elverum–Trysil–Faemund; Stenkjaer–Namdalseid; Sjøveien–Saetermoen–Finsnes; Vardø–Vadsø–Tanen.

There were two Norwegian automobile factories in 1921, but both imported finished parts.

*State-Subsidised Steamer Services.*—In the inland State-subsidised steamer services it was necessary during the war to make restrictions from 1915, and in 1917 freights had to be materially increased, both on coast and local routes. These restrictive measures especially affected northern Norway (the provinces of Nordland, Tromsö, and Finmark) whose communication with the rest of the country became greatly restricted. In 1917 it became necessary to impose very considerable extra taxation on the public to maintain the necessary service, especially on the northernmost portions of the country. From Feb. 1917 to the end of Nov. 1918 steamer services between Bergen and Newcastle were entirely stopped, and the same was the case with the Christiania–Fredrikshavn route from the end of April 1917 to the end of Oct. 1918. When the contracts with the coastal service companies expired on July 1 1921 the State contribution to this service was materially reduced. For the financial year 1921–2 the State contribution to the northern Norway routes was placed at about 11,500,000 kroner. The Bergen Steamship Company in 1921 established an express route between Newcastle-upon-Tyne and Bergen with railway connection to London and Christiania, so that travellers between these two places were able to do the journey in 70 hours, of which 22 were on the sea.

*Tourist Traffic*, which prior to the World War had been a source of revenue of no little importance, was practically entirely suspended

during the World War. It failed in 1915, revived a little in 1917, but in 1918 was again less and the few foreign travellers were practically all Danish and Swedish. There were many of these in 1919 and 1920 and besides them, as before the war period, a large proportion of inland travellers. But in 1921 the character of the traveller traffic changed, in that it consisted again of a great stream of foreigners, Americans, Englishmen and Hollanders, the latter due no doubt to the fact that in Aug. 1921 the Queen of Holland travelled through the tourist centres of Norway. In April 1921 a Norwegian State Railways Travel Bureau was opened in Norway House, London, which acts as a central office for tourist traffic to and from Norway and England. The big English "floating hotels" in 1921 resumed their visits to the westland fjords of Norway.

*Telegraphs and Telephones.*—Telegraphs and telephones have been very thoroughly developed during recent years, especially wireless. The management of the State telephones is combined with that of the State telegraphs, at the head of which there is a Director of Telegraphs, who is under the direct jurisdiction of the "Trade Department" (properly "The Department for Trade, Sea Transport, Industry and Fisheries," established by decree of the Storthing of June 28 1916). In 1912 the Storthing approved a plan submitted by the then Director of Telegraphs (Thomas Heftye, born 1860, killed in the railway disaster at Trondhjem Sept. 19 1921, Director of Telegraphs from 1905, formerly a minister of State, senior lieutenant in the engineer service), whereby in the course of a few years by an extraordinary appropriation a telephone trunk-line would be constructed from Trondhjem to Vadsö. At the end of 1919 the main line was ready northwards to Tromsö and lines were extended for local telephone service from different points in East Finmark, with branch-lines to the islands and fishery properties and northwards to the regions inhabited by the Lapps. In 1921 the Storthing made an extraordinary appropriation, outside the usual construction budget, for district lines in the few parts of the country still without telegraph or telephones. In 1921 there was a telephone on nearly every farm.

The first two radio-telegraph stations, Sørvagen and Røst, were opened in 1908 in the Lofoden fisheries district; in 1910 the Telegraph Service took over from the navy the Tjöme station in the outer part of Christiania Fjord, and Flekkerøy, a little southwest of Christiansand. In 1911 came the more powerful stations, on the Rundemanden in the neighbourhood of Bergen, and at Ingøy, a little to the north of Hammerfest. In connexion with this, the Norwegian Government in 1911 erected a post-office and radio-telegraph station at Ankershavn, on the eastern side of Green Harbour, Spitzbergen; later a mining company erected four smaller stations in West Spitzbergen, which are connected with Norway through this Spitzbergen central station. In Aug. 1919 a wireless station was erected at Ostervaag on Björnöya (Beeren Island), also by a private mining company. And in Sept. 1921 a station of the Norwegian Radio Company established mainly for daily weather forecasts to Reykjavik, Ingøy, and Fauske was opened on Jan Mayen. All these stations are comparatively small. However, Norway obtained one of the world's largest wireless stations (Marconi system) in the autumn of 1919 in Stavanger, intended for direct communication with stations in North America. Lastly there are powerful new stations on Tryvanshøiden near Christiania, Udsire on the island of the same name south-west of Haugesund, at Bodö in Fauske province, a little to the east of the town Bodö, and in 1921 the construction of a large station close to Trondhjem was begun. The stations at Tromsö and in the neighbourhood of the head of Varanger Fjord have been taken in hand and with the Bodö, Trondhjem and Christiania stations will form a trunk system of wireless telegraphy over the whole country.

*Shipping.*—Before the World War the Norwegian merchant fleet ranked fourth in the world with a total gross registered tonnage of about 2,600,000. In proportion to the population Norway's commercial fleet was greater than that of any other country. The war has essentially altered this position. Nearly half the Norwegian fleet was sunk and 1,200 non-combatant Norwegian seamen perished. Nevertheless the Norwegian fleet was in 1921 about as big as before. In the second year of the war several hundred thousand tons of new and old ships had already been purchased from foreign countries, and new vessels were contracted for in various parts of the world. It is calculated that between one-third and one-half of Norway's tonnage in 1921 has been built within the three or four preceding years. This new fleet was constructed without Government subsidy. The sudden and violent derangement of values in 1920, however, brought many of the ship-owning firms, who had to replace their war losses at top prices, into serious financial embarrassment. Before the war only 10% of the Norwegian fleet was engaged in traffic with Norway; the majority ran on more or less regular routes between foreign ports. Regular liner traffic on fixed routes had developed rapidly, but was stopped by the war. After the war the lost ground was quickly regained, and the tonnage owned by the liner companies increased by the addition of new vessels especially built for regular-line service. Several new lines were also started. The tonnage of vessels engaged in regular-line traffic was 130,340 gr. reg. tons in 1910, 298,275 gr. reg. tons in 1916 and 400,000 in 1920. The development of the regular-line trade was thus satisfactory, but nevertheless the total tonnage owned by the liner companies was in 1921 not more than ⅓th of Norway's total ocean-going tonnage.

The greater part of the Norwegian tonnage was operated on a time charter (tramp) basis before the war. The war brought a change also in this respect and in other ways altered the conditions of employment. Norwegian ships were withdrawn from trades which had previously absorbed a great deal of Norwegian tonnage, as for example the trade between India and China, the West Indies trade, the Black Sea trade, etc. The British coal trade laid claim to most of this tonnage. Thus in the summer of 1916 no less than 159 Norwegian ships with a total tonnage of 173,119 gr. reg. tons were constantly running in the coal trade between England and France alone, and national supplies required three times as much Norwegian tonnage as was necessary before the war.

Over 26,000 men (sailors, firemen etc.) and officers (masters, mates and engineers) were in 1921 employed aboard the vessels of the Norwegian merchant fleet, and about 17% (more than 112,000) of the entire male wage-earning population (about 660,000) earn their living directly or indirectly by the sea.

Norway's maritime laws are in advance of the legislation of most other countries. This applies in particular to provisions concerning the crews and their conditions of work. An act of July 11 1919, which came into force Jan. 1 1920, established the daily hours of labour on board Norwegian ships in harbour at eight hours, in the tropics seven hours, between 7 in the morning and 5 in the afternoon. At sea the work of the deck is divided into watches throughout the 24 hours in the usual manner. The work of the engine-room crew was, however, to be divided into three watches in the 24 hours to such extent as the number of men permits. By an Order in Council of May 31 1918 a manning schedule for Norwegian vessels was established, giving the number of mates, engineers and hands according to the size of the vessel. The two-man cabin system has also been adopted, and sanitary arrangements to meet the strictest hygienic requirements are obligatory.

In several Norwegian ports (especially in Christiania, Christiansand, Stavanger, Bergen and Trondhjem) the harbours have been considerably extended and modernized. The question of establishing a free harbour has been discussed in all these cities and on June 20 1919 the Government appointed a committee to examine whether a Norwegian free harbour ought to be established and if so, where. This committee reported in Oct. 1921. It recommended the construction of a free harbour, calculated to cost 31,000,000 kr., between two of the islands in the fjords near Christiania.

*Water-Power.*—Since electrical power transmission opened the way to bringing great quantities of power to suitably situated industrial centres, it has become possible to utilize Norway's greatest natural asset, water-power. It has been the foundation for the industrial development of the 20th century in Norway. Though Norway itself lacks coal, she has come forward into the front rank of power-producing countries. No country in Europe has nearly as great wealth of water-power, not only in proportion to the population, but absolutely. And this power is the cheapest and most conveniently distributed in the world. The total water-power of Norway is estimated to amount to at least 15,000,000 H.P., which with reasonable regulation and development can be utilized the year round, day and night. More than half of this power is admirably situated for big industries, as the fall of the water in many cases is direct into deep fjords, where power stations, factories and quays can be erected in ice-free, well-sheltered harbours, available for the largest ships. As a result of the sharp steep slope on the west of the country, the Cascades in the Westland and northern Norway not infrequently have a fall of 1,500–3,000 ft., often in connexion with large high-lying inland lakes, which permits of practical and effective storage of water and renders the regulation of the flow economical and convenient.

Of the 15,000,000 H.P. available the Norwegian Government owns about 2,000,000, of which about 75,000 H.P. is developed, and a corresponding amount of power is owned by Norwegian communes, but the rest are in private ownership, either of single persons or companies. About 1,200,000 H.P. had been developed by 1921, of which 250,000 H.P. are used to supply the general requirements of lighting, household purposes, agriculture, trade, small industries, tramways, etc., while about 95,000 H.P. are used in large industries. A further 250,000 H.P. were under development in 1921 primarily for public and communal purposes. The increase in the requirements of the country is shown by the following figures: in 1907 about 250,000 H.P. had been developed, in 1913 about 750,000 H.P. and in 1920 upwards of 1,200,000.

A portion of this store of power will be available for transmission to central Europe, poor in water-power. The scheme was in 1921 so far advanced that already the Governments of Norway, Sweden and Denmark had appointed a commission of experts to investigate the question of the transmission of power from Norway, through Sweden to Denmark. And from Denmark, it is not a long extension to Germany. The distance from Norway to Denmark and Germany is 300 and 450 miles respectively. The fact that in 1914 five times as many water H.P. were employed as steam H.P. in metal industries and mechanical workshops is evidence of the part water-power already plays in the industries of Norway as compared with imported coal. In the textile industries likewise about 5 times, in the paper industry 10 times, in the foodstuffs industry 4 times, and in mine workings double as many water H.P. as steam H.P. are

employed, and in the chemical industry water-power is employed (about 400,000 H.P.) almost exclusively. The total installation of the country for electric light and power in 1921 represented over 800,000 water H.P. as against only 40,000 steam H.P.

*Industrial Use.*—For the electro-chemical and electro-metallurgical industries in particular, water-power is of the utmost importance in the utilization of the raw products of the country. Systematic investigation has revealed that raw materials are relatively abundant, and especially has it been established that the country is far richer in iron ores than was supposed. This wealth formerly could only be partly utilized, as the ores were low-grade. The steadily increasing need for raw material, together with improved technical methods of production, gives hopes, however, for the utilization of poor or contaminated ores by economical working. The introduction of the electric smelting-oven opened up the possibility for development of an iron and steel industry in Norway based on the country's own metals. The importance of this appears when it is considered that Norway possesses iron ore roughly calculated to amount to about 1,500,000,000 tons—mining to a depth of from 500 to 600 ft. below the surface. By surface-working about 350,000,000 tons of ore can be obtained. The ore in northern Norway is, however, poor—containing only 30–37 % of iron. In middle Norway there are about 20,000,000 tons of ore with 55 % iron and in the south about 5,000,000 tons with 45–48 % iron. Norway also possesses a large supply of low-grade zinc ores, which, in the future, will certainly be used. Even now the country has a not unimportant zinc industry based on imported raw material. Norway also has an aluminium industry supplied with imported raw material (bauxite). As, however, Norway possesses a vast supply of aluminium silicate and other deposits rich in aluminium, it can be assumed that an important aluminium industry will be developed on the country's own raw material. The most important mining industry of the country before the war was the mining of copper ore and iron pyrites, large deposits of these minerals occurring in middle and northern Norway. These ores were exported as raw material, but the extraction of the metal should form a new industry. A large nickel refinery has been established near Christiansand. Among other ores found which are important in connexion with the development of new branches of industry—either independently or in relation to the iron and steel industry—are those containing chromium, silicon, nickel, titanium, and others. There was a great increase in the production of molybdenum during 1920.

Already by 1921 the results attained in the chemical industries in the course of a few years were impressive. Particularly in the manufacture of artificial fertilizers such as Norwegian saltpetre, calcium nitrate and cyanamide. The raw materials for the manufacture of saltpetre are atmospheric nitrogen and limestone. The greatest electro-chemical establishment is Norsk Hydro-elektrisk kvaelstof-aktieselskap at Rjuhan; this factory was using over 200,000 water H.P. in the preparation of Norwegian saltpetre, nitric acid, nitrate of ammonia, nitrate of soda and other products. The new synthetic saltpetre industry which was originated and developed in Norway on the Birkeland-Byde'ske methods also supplies raw material for the explosive and dye-stuff industries. The production of carbide of calcium has also made great strides. The value of the country's products in the electro-chemical and electro-metallurgical industries reached in 1918 to over 180,000,000 kroner.

*Finance.*—Since 1905 the Norwegian State budget has been divided into two chief sections, one embracing the ordinary, the other the extraordinary revenue and expenditure. By a measure adopted by the Storthing in 1907 the financial year was altered from April–March to July–June. In 1911 the Storthing passed an amendment to the constitution by which Norway was under ordinary conditions to have a fixed unassailable reserve of 40,000,000 kr. (at that epoch estimated to have a value of £2,222,222).

The eight budget years July 1 1906 to June 30 1914 in all but one period (1909–10) gave a surplus, which altogether amounted to 55,900,000 kr. at the end of this period; the greater part of this amount being applied to various defensive measures. During these 8 years the national debt increased by only 15,000,000 kr., from 342,400,000 to 357,400,000 kroner. At the end of the budget year 1913–4 the cash reserve of the national exchequer amounted to 50,200,000 kroner. These figures show that the financial position of Norway was sound at the outbreak of the World War. For the budget year 1914–5 the State revenue amounted to 197,000,000 kr., of which 167,800,000 was on the ordinary, and 29,500,000 on the extraordinary budget; expenditure amounted to 186,400,000 (ordinary 156,100,000, extraordinary 30,200,000) and the remaining surplus was therefore 10,600,000 kroner. In this connexion it should be noted that expenditure incurred for the maintenance of neutrality was not included in the budget, but during the whole war was provided for apart from it. The national exchequer cash reserve at the end of this budget year amounted to 35,700,000 kroner. In 1915–6 revenue increased to 240,400,000, and expenditure to 191,200,000, showing a surplus of 49,200,000. Under the pressure of the general panic which was prevalent during the first year of the World War at the increase of the budget, measures were taken to reduce the budget expenditure; but the gloom was only of short duration, and was succeeded in 1915 by a period of prosperity, which caused the national revenue to increase far beyond the estimate. Income and property taxes that year realized 24,600,000 more than had been estimated, customs 7,700,000 more, etc. The exchequer surplus on June 30 1916 amounted to 57,100,000 kroner. This progress continued the following year, 1916–7, when the national revenue rose to 394,700,000 while the expenditure was only 268,700,000, and a clear surplus remained of 126,000,000 kr., treble the amount of the national budget a few years earlier. Income and property tax for that year together yielded 86,300,000 more than estimated, customs 13,800,000, and a war-period tax added to the revenue on the extraordinary budget realized 36,600,000 kroner. The treasury had at the expiration of the budget year a reserve of 80,800,000 kroner. The budget for the financial year 1917–8 was balanced at an amount of 446,400,000 kroner, 250,300,000 on the ordinary, 196,400,000 on the extraordinary. But the ordinary revenue attained 406,200,000 and the extraordinary 213,600,000, a total of 619,800,000 kroner. At the same time the expenditure increased to a total of 501,800,000 kr. (ordinary 296,100,000, extraordinary 205,600,000), and a surplus remained of 118,000,000 kroner. Among the assets on the ordinary budget income and property taxes showed an amount of 150,700,000 (against an estimated 58,600,000), stamp duties (principally from stock transactions) 40,100,000 (against an estimated 12,000,000). On the extraordinary budget, war tax showed 160,300,000 (against 114,200,000 estimated), and among the expenditures on this part of the budget appeared 31,300,000 kr. for increased cost-of-living bonuses to State officials, with 106,600,000 for other expenditures in connexion with increased costs; the extraordinary expenditure on defence was 26,000,000 kr., which was entirely met by the war tax and tonnage duty. The Treasury reserve at the end of the budget year amounted to 187,100,000 kroner. The budget for 1918–9 was balanced at 625,000,000, 333,300,000 on the ordinary and 291,700,000 on the extraordinary. The ordinary revenue however reached 463,000,000 and the extraordinary 324,600,000, together amounting to 787,600,000 kr.; the expenditure rose to 672,200,000, a surplus therefore accruing of 115,400,000 kr. Among the expenditures on the extraordinary budget the cost-of-living bonuses increased to 89,500,000, and other measures in connexion with increased costs 139,300,000 kr. The Treasury reserve was 260,200,000 kroner. For the financial year 1919–20 the budget was balanced at 726,500,000 (392,400,000 on the ordinary and 334,100,000 on the extraordinary). On the extraordinary budget credit-side that year were presented loans (for railway, telegraph and telephone construction, also purchase and development of waterfalls) 60,300,000, war tax 236,300,000 and tonnage duty 17,400,000 kroner. Among the expenditures on the extraordinary budget were:—cost-of-living bonuses, 100,700,000; other State expenditure caused by increased costs, 88,000,000; losses by emergency measures affecting industries, 25,000,000; and measures against unemployment, 8,000,000 kr.,—a surplus of 42,300,000 remained. The ordinary budget for 1920–1 was balanced at 492,400,000 and the extraordinary at 267,400,000 kroner. The preceding figures are gross totals derived from national accounts and budgets, while the surplus stated is estimated and does not quite correspond with the actual reserve. The net figures, *i.e.* the figures which show the difference between the revenue and expenditure relating to the various State purposes, present a somewhat different picture. The extraordinary budget was in 1921 swollen more than the ordinary; before the war this part of the budget included especially expenditure on railway construction, carried out by means of loans. During the war this budget included expenditure on extra defensive measures, and the greater part of the expenditure caused by the increased costs. The expenditure incurred in the maintenance of neutrality, on the other hand, was not included in the budgets. Taking this expenditure into account also, the following were the amounts used extraordinarily:—1914–5 61,000,000; 1915–6 59,300,000; 1916–7 139,800,000; 1917–8 272,500,000; 1918–9 351,200,000; 1919–20 334,000,000. For the six budget years dealt with above 1,218,000,000 kr. were therefore devoted partly to expenses normally raised on the extraordinary budget, and partly to emergency expenditure,—for example, shortage on herrings, fish and fats which the State took over, shortage on corn and shortage caused by the assumption of war risks for fishing and whaling vessels. The surplus for 1914–9, totalling 385,900,000 kr., was used for meeting current State expenditure.

The Norwegian Government had the following "war income" at command:—(1) the afore-named surplus on the ordinary budget, 385,900,000 kr.; (2) war-period tax, total 653,200,000 kr.; (3) tonnage duty, a special tax on shipping, 75,200,000 kr.; (4) other extra revenue, 12,000,000 kr.: altogether, 1,126,300,000 kr. The total amount of the tax revenue in 1914–5 was 178,600,000 kr., and in 1917–8 it was 639,400,000 kr. In order to increase the revenue, the Government took refuge during the war in a series of new taxes and, in part, greatly increased those already in existence. Thus in 1915–6 a material increase in income and property tax was decreed, with heavier incidence on larger incomes and property, stamp duty was also increased, and, as new taxes, a stamp duty on tobacco and a match tax. All these taxes were later increased and remained in 1921, except the match tax which was abolished in 1917. In its place a transient luxury tax was imposed, which however proved to be disappointing. In 1915 a war-time tax was introduced which produced 236,300,000 kr. in 1919–20. In 1916

a tonnage duty was imposed on shipping as a special tax, and this up to July 1919 had realized about 75,000,000 kr., which was used for measures against scarcity. The expenses-of-neutrality service (maintaining the neutrality of the country, principally along the coast with the aid of the navy) cost in 1914–5 21,800,000; in 1915–6 27,200,000; in 1916–7 41,300,000; in 1917–8 55,800,000, and in 1918–9 35,300,000 kr.; or a total of 181,400,000 kr.

On June 30 1914 the Norwegian national debt amounted to 357,400,000 kr., for the greater part long-period (50–75 years) loans with 3, 3½ and 4% interest. Of this debt 336,500,000 was in foreign countries and 20,900,000 in Norway. Up to the end of 1919 four fixed loans were adopted, three with a total amount of 225,000,000 in the country itself, and one—18,600,000 kr. in amount, repayable in 1923—in the United States. There were in addition some short-term repayable loans of smaller amounts taken up in America and England. On Dec. 31 1919 the fixed national debt had increased to 594,300,000 kr. To this must be added the cash credits opened in 1918–9 by the different Norwegian banks for the purposes of financing trade, which brought the floating debt of the State at the end of 1918 up to 422,500,000, a total national debt therefore of 1,016,800,000 kr. The yearly installment and interest on the fixed national debt, which in 1914–5 amounted to 17,500,000 kr., had in 1920–1 increased to double, 34,700,000 kr. A new loan in 1920–1 brought the national debt on Dec. 31 1920 up to a total of 1,167,000,000 kr. or 440 kr. per head of the population. During the war period it was maintained as an invariable principle that fixed loans could only be applied to reproductive purposes—construction of railways and telegraph lines, building of power stations, purchase of waterfalls and industrial construction. To such purposes nearly 500,000,000 kr. was applied in 1921. In addition the State possesses all goods purchased and stored for the provisioning operations and not liquidated, up to Oct. 1921 to an amount of at least 100,000,000 kr. Finally the amount the State was owed abroad (especially by Germany) was at least 150,000,000 kr. for goods supplied—principally fish.

The Norwegian communes occupy a very independent position as regards the State, not only in political constitution but in economic finances. They have, practically speaking, full self-government. The approval of the Government is only required for the putting into operation of such economic measures as bind the finances of the commune for a long period of years, *e.g.* all communal loans. Taxes in the communes have increased to an extraordinary extent. For all corporate townships and cantons together they amounted in 1910 to 45,840,000 kr.; in 1914–5 to 65,190,000 kr., and 1919–20 to 322,280,000 kr. In 1920 new communal loans to a total of 350,000,000 kr. were adopted, or about as much as the whole of the total communal debt on June 30 1917. In 1921 the total communal debts amounted to 1,000,000,000 kr. This money has however been used mainly for reproductive purposes—electric works, gas and water supply and the like. In 1914–5 every taxpayer in the towns paid 130·90 kr. in communal taxes, which amounted to an average of 50·07 kr. per head of the inhabitants. In the budget year 1918–9 these figures increased to 579·34 kr. and 247·69 kr. respectively. In the cantons the corresponding figures were (1914–5) 49·60 kr. and 16·61 kr., (1918–9) 133·75 kr. and 46·02 kr.

A measure of how property and incomes have increased in Norway is afforded in the assessments of the position of the whole population as regards income and property, which are compiled every year in every town and in every canton by a specially appointed local commissioner, who critically investigates the taxpayers' own statements regarding their economic position, or independently estimates it. The "tax list" compiled in this manner contains the names of all the taxpayers, with a statement of the "presumed" income and property and the "rated" tax for each individual. Though punishments for incorrect "personal declarations" are very stringent and appraisement can often be defective, especially in the country by underestimation of the taxpayers' economic ability, the reflection of the economic assessment of the whole country as shown by the total amount of taxation must, roughly regarded, be just.

The figures only apply to the portion of the population which comes under the taxation laws, but the additions for the persons who are without the scope of this are not important. On these calculations the following statement may be given of the total national property and income:—

| | Number of Taxpayers | Property Million Kr. | Income Million Kr. |
|---|---|---|---|
| 1911 | 732,158 | 2,693·4 | 609·2 |
| 1913–4 | 808,113 | 3,852·0 | 830·7 |
| 1917–8 | 919,494 | 7,332·5 | 2,273·4 |
| 1918–9 | 976,252 | 10,153·6 | 2,827·7 |
| 1919–20 | 998,413 | 11,819·2 | 3,173·4 |
| 1920–1 | 1,032,537 | 12,678·9 | 3,701·8 |

(K. V. H.)

*Agriculture.*—According to official statistics for 1917 (the latest issued in 1921) the agricultural area amounts to 2,430,000 ac. and the area suitable for agriculture to some 1,740,000 ac. Between 1918 and 1921 at least some 50,000 ac. were laid under the plough, the percentage being highest in the counties of Rogaland (5,000 ac.), Nordland (nearly 5,000 ac.), and Hedmark (4,000 ac.), and lowest in Finmark (with only about 250 ac.). During these years the Storthing devoted over 26,000,000 kr. to new cultivation. The characteristic feature in Norwegian agriculture between 1900 and 1920 was the constant increase of small freeholders having for their speciality the cultivation of root crops and feeding of cattle.

The cultivated area in 1917 was made up as follows:—612,560 ac. fields, 1,100,000 ac. meadows on cultivated soil, 24,000 ac. gardens. In 1919 the crops amounted to the following figures: 29,000 tons wheat, 25,000 tons rye, 115,000 tons barley, 220,000 tons oats, 22,000 tons mangcorn, a total of 411,000 tons of grain, together with 1,000,000 tons of potatoes and 1,700,000 tons of hay.

The total holding of live stock in the country for the dates given was:

| | *Dec. 31 1907* | *Jan. 1 1918* |
|---|---|---|
| Horses | 170,325 | 208,219 |
| Large stock | 1,027,520 | 1,085,707 |
| Sheep | 991,211 | 939,940 |
| Goats | 222,717 | 185,800 |
| Swine | 163,467 | 127,230 |

According to the prices obtaining in Norway in 1918 the live stock holding for that year had a value of 1,038,000,000 kr. (horses 317,000,000 kr., large stock 567,000,000 kr., sheep 84,000,000 kr., goats 12,000,000 kr., swine 47,000,000 kr.). To this must be added, reindeer 11,000,000 kr., feathered stock 14,000,000 kr., bee stock 1,500,000 kr., and rabbits 500,000 kr.

The following are the figures for dairies and milk-condensing factories:—

| | *1913* | *1919* |
|---|---|---|
| Number of dairies and factories | 677 | 460 |
| Milk received in millions of kilograms | 308·15 | 212·49 |
| Amount paid for milk, in million kroner | 33·13 | 94·87 |
| Amount paid for milk per kgm. (in öre) | 11·35 | 45·22 |

The total area of forests is approximately 26,640 sq. m. (69,000 sq. km.), representing a value of about 1,000,000,000 kr. Upwards of 61·4% of the forests are grown with pine and fir trees. The export value of forestry products in 1911–5 averaged annually 92,300,000 kr., and in 1916–9 186,000,000 kr. Exports of planed, cut, shaped and round timber in 1913 amounted in value to about 34,000,000 kr., exports of wood-pulp and cellulose to about 52,000,000 kr., and of paper to about 32,000,000 kr., or altogether about 120,000,000 kr. for forest products. In 1920 there were exported 386,000 tons of wood-pulp as against 496,000 in 1913, 211,600 tons of cellulose against 211,000 tons in 1913, 194,000 tons of paper and pasteboard against 184,000 in 1913, and a total of about 940,000 cu. metres of timber of all kinds against 1,044,000 cu. metres in 1913. Forestry progress is largely due to the Norwegian Afforestation Association (founded 1898), which has planted annually between 10 and 15 millions of new trees since about 1906.

*Fishing Industry.*—The fisheries are among the principal economic resources of Norway. It is calculated that nearly 100,000 men (1917) are engaged in them. Up to the close of the 19th century Norwegian fisheries generally retained the character of coast fisheries which they had had for centuries. Since then a great change has taken place and the great bank fisheries, carried on by fishing steamers and motor vessels chiefly from Aalesund (about 16,500 inhabitants), have become important. The Norwegian fishing fleet consisted in 1917 of 267 steamers, 11,048 motor vessels and about 40,000 sailboats, with an approximate total value of 100,000,000 kr. In 1917 the total yield of the coast fisheries was valued at 135,000,000 kr.

By law of Aug. 1 1919 the Storthing decreed that a Norwegian State Fisheries Bank should be established to finance the Norwegian fisheries, with a State-provided capital amounting to at least 5,000,000 kr. and a reserve fund of 750,000 kr. The object of the bank was (1) to grant loans for providing, rebuilding or repairing fishing vessels, (2) to arrange mortgages on fishing vessels, (3) for constructing or rebuilding icehouses, refrigerators, drying works, or making similar arrangements for the protection or improvement of fish products, (4) for the consolidation of fisheries by the provision of fishery appliances, equipment, etc. In terms of the law the bank is required to have its head office in the town where the Fisheries Directorate has its seat (therefore in Bergen), but loan offices may be established in such places as the king (Government) may decree. It is stipulated that in such places a union must be constituted of at least 50 members who hold themselves jointly and wholly responsible for the amount loaned to members. The administration of the bank consists of three members, with the Director of Fisheries as permanent adviser. The Fisheries Bank commenced operations in Nov. 1921. A State loan of 15,000,000 kr. was granted for the purpose.

*Whaling Industry.*—Scandinavians have recently taken a leading place in the whale-fishing industry. The pioneer was Svend Foyn (1809–1894), who introduced new methods into the industry; and since the discoveries of fishing fields in the Antarctic in 1906–7, whaling has developed in the South Atlantic and in several other parts of the world as well. The total production of whale-oil by Norwegian whaling stations amounted in 1908 to 69,000 bar., in 1911 to 344,000 bar., in 1913 to the "record" of 600,000 bar., in 1915 to 475,000 bar., in 1917 to 231,000 bar., in 1919 to 163,000 bar., and in 1920 to 212,000 bar. (6 bar. = 1,000 kgm. = 1 ton). The number

of fishing companies was greatest in 1912, when there were 60, with 34 land stations and 39 floating boiling plants and 160 whaling vessels. The total value of oil from the different fields (S. Shetland, S. Georgia, N. and S. America, E. and W. Africa, and the northern seas,—Ireland, Hebrides, Faroes, W. coast of Norway and Spitzbergen) was (in millions of kr.) 4·5 in 1908, 15·8 in 1910, 29·1 in 1912, 34·5 in 1914, 35·5 in 1916, 28·5 in 1918, and about 60,000,000 kr. in 1920. Whaling is operated chiefly from the towns of Sandefjord, Tonsberg and Larvik. The share of Norway in the world's production of whale-oil amounted to nearly 50% in 1920.

*Mining.*—Norway is not an especially rich mining country, the ores and minerals being mostly of poor quality. The oldest and most important branch of mining industry is the working of copper ore and sulphuric pyrites, large quantities of which are extracted at Löken in the district of Meldalen, at Roros and at Sulitelma, while more scanty supplies are met with at many places, especially S. and E. of the Trondhjem Fjord. The production of iron ore increased rapidly after the beginning of the 20th century, and in 1915 it exceeded in weight that of copper ore and pyrites; in 1906–10 the production of the former was 72·3% and of iron ore 24·5% of the total mineral production in weight, whereas in 1911–5 the proportions were 46·3% and 48·4% respectively. On the other hand the value of the copper ore and pyrite products in 1906–10 was 81·3% and of iron ore 10·5% of the total value of production, and in 1911–5 the proportions were 63 and 29% respectively of the value produced. However, the production of iron ore will doubtless play a steadily increasing part, partly because of the extensive deposits of iron, chiefly in N. Norway, estimated by official experts at 175,000,000 tons, yielding about 100,000,000 tons of iron, partly because of the rapid development of the electrolytic methods for the smelting of iron ore, two important plants having actually been laid down for this industry, one at Ulefoss (1910), another at Tinnfoss, both in Telemark county. During 1914–6 the latter had an average yearly production of 6,300 tons of iron. For the present the exportation of iron ore has a far greater importance than the production of iron, export taking place from the vast deposits in northern Norway between Pasvikelven on the E. and Langfjorden in the W., with the great undertaking in S. Varanger, E. Finmark. During the period between 1905 and 1910 separation works were constructed here with quays, railways, etc. for export on a large scale, which commenced in 1910 and already in 1913–5 amounted to about 550,000 tons of slack and briquettes yearly. The number of workers employed at that period was 1,350.

In addition to copper and iron, silver is found in Norway at Kongsberg, nickel at Evje in Setesdal a little N. of Christiansand, titanium ore at Kragero, Arendal, Ekersund and Tvedestrand, while there are stone quarries of different kinds in many places, but mainly round about Fredrikstad and Fredrikshald, Östfold county; from here stone is supplied to the quays at Rosyth. Roofing slates are quarried in Valdres and at Voss. Digging and stone industries in 1914 occupied 6,556 workmen and in 1918 8,424. The weight of the total production of minerals and ore in 1914 was 1,210,000 tons and in 1918 540,000 tons, the values being 22,720,000 kr. in 1914, and 37,130,000 kr. in 1918. The value of the production from the mining works from the beginning of the century up to and including 1918 amounted to a total of 375,000,000 kroner.

*Manufactures.*—Norwegian industry was up till about 1890 essentially based on home consumption. But when the problem of the conversion of water-power into electric power was solved, it began to develop on an export basis. A rapid development during the ten years following 1890 was followed about the end of the century by a period of decline, which continued till 1904, when the first indication of a new and still greater advance manifested itself. The culminating point was reached in 1917, and during 1918 a period of depression again set in, which was still prevalent during 1921. A scale for the growth of industry is provided in the number of work-years (of 300 working-days) indicated by the aggregate of the country's industries, the figures being 92,000 in 1897 and 214,000 in 1918, an increase of about 133%. Progress, however, more clearly appears from the statistics of the amount of wages paid, which amounted in 1897 to 72,000,000 kr. and in 1918 to 619,000,000 kr.; the increases here were up to 1910 103%, to 1914 225%, and to 1918 756%. The average yearly wage of a workman was 785 kr. in 1897, 987 kr. in 1908, and 2,886 kr. in 1918, per working-year. After 1918 wages rose to treble what they were that year.

In 1897, out of 9,422 industrial works 3,799 or about 30% had mechanical motive-power; in 1917 about 55% of the 20,375 industrial works possessed mechanical motive-power, electric motors included; while during 1897–1918 the population rose 23%, the average number of persons engaged in all groups of industry rose 98·8%.

| Numbers of persons employed in industries (in thousands) | | Increase % | Population of the country (in 1000's) | Increase % |
|---|---|---|---|---|
| 1897 | 70 | .. | 2,157 | .. |
| 1905 | 87 | 25 | 2,315 | 7 |
| 1910 | 112 | 60 | 2,395 | 11 |
| 1915 | 136 | 94 | 2,509 | 16 |
| 1917 | 148 | 112 | 2,629 | 22 |
| 1918 | 139 | 99 | 2,655 | 23 |

In spite of the immense growth of Norwegian industry, the annual value of imports increased during 1911–5 to a yearly average of 596,000,000 kr., while in 1915–8 it reached an average of 1,400,000,000 kroner.

*Value of Imports.*

| | For consumption % | For production % |
|---|---|---|
| 1896–1900 | 58·4 | 41·6 |
| 1906–1910 | 52·9 | 47·1 |
| 1918 | 36·8 | 63·2 |

The most important industrial commodities exported are: (1) pulp, cellulose and paper, (2) products of the mining industries, (3) electro-chemical and electro-metallurgical products, (4) canned goods. In 1913 the products of these branches of industry represented 89% of the export trade. The following tables show in which direction the various branches of industry developed during the World War:—

*Industrial Exports: in million kroner.*

| | Total value | Pulp, Cellulose, and Paper | Ores | Electro-chem., Electro-metal. prod. | Canned Goods |
|---|---|---|---|---|---|
| 1913 | 193·6 | 83·9 | 18·5 | 45·0 | 25·7 |
| 1916 | 536·1 | 169·7 | 32·5 | 182·7 | 51·3 |
| 1917 | 520·0 | 137·5 | 26·1 | 216·0 | 63·5 |

*Distribution of Imports and Exports.*

| Countries | Percentage of Norway's imports | | Percentage of Norway's exports | | Percentage of total trade of Norway | |
|---|---|---|---|---|---|---|
| | 1913 | 1918 | 1913 | 1918 | 1913 | 1918 |
| Germany | 29·80 | 11·01 | 20·84 | 11·27 | 26·02 | 11·11 |
| Great Britain & Ireland | 24·76 | 28·96 | 24·31 | 41·45 | 24·57 | 33·65 |
| Sweden | 14·35 | 17·66 | 6·19 | 12·84 | 10·91 | 15·84 |
| United States | 6·64 | 15·94 | 7·95 | 0·93 | 7·19 | 10·30 |
| Other Countries | 24·45 | 26·43 | 59·29 | 33·52 | 31·31 | 29·11 |

How the turnover of Norwegian trade increased during the present century appears from the following table (some figures for the previous century being given for comparison):—

| | Imports million kroner | Exports million kroner | Total | Value per inhab. in kr. | | |
|---|---|---|---|---|---|---|
| | | | | Imports | Exports | Total |
| 1861–5 | 75·0 | 54·5 | 129·5 | 45·75 | 33·22 | 78·97 |
| 1881–5 | 158·2 | 114·8 | 273·0 | 82·40 | 59·80 | 142·20 |
| 1901–5 | 289·0 | 183·5 | 472·5 | 127·89 | 81·19 | 209·08 |
| 1911–5 | 596·4 | 422·7 | 1019·1 | 246·96 | 175·02 | 421·98 |
| 1916 | 1353·7 | 988·3 | 2342·0 | 542·11 | 395·81 | 937·92 |
| 1917 | 1661·8 | 791·4 | 2452·7 | 647·93 | 308·65 | 956·58 |
| 1918 | 1252·6 | 755·0 | 2007·6 | 477·35 | 287·75 | 765·10 |
| 1919 | 2583·7 | 782·1 | 3365·8 | .. | .. | .. |
| 1920 | 3029·9 | 1241·8 | 4271·7 | .. | .. | .. |

The import value of the most important goods in 1920 was as follows (in million kr.):—grain 260, meat and pork 53·6, eggs 14·3, sugar 113·7, coffee 31·5, clothing 66·7, shoes and boots 44·2, woollen ware 128·9, cotton goods 128·4, silkware 19·2, coal and coke 343·5, petroleum and benzine 65·4, metals 310·6, fertilizers 10·6, machinery 102·2, ships 367·2, automobiles 45 and wine 46·2.

The values (in million kr.) of the most important exported goods in 1920 were:—fish 158·9, canned goods 40·4, fish-oil 26·2, condensed milk, etc., 13·1, timber 109·8, wood-pulp and cellulose 224·6, paper 222, artificial fertilizers (Norwegian saltpetre) 60·4 and ships 42·2. In addition, foreign goods to the value of about 59,000,000 kr. were reëxported.

A calculation of the value of foreign trade based on the prices obtaining in the normal year of 1913 gives the following results:—

| | Imports million kroner | Exports million kroner | Imports Index fig. | Exports Index fig. |
|---|---|---|---|---|
| 1913 | 339·3 | 252·9 | 100 | 100 |
| 1920 | 518·3 | 218·5 | 153 | 86 |
| 8 months 1921 (Jan.–Aug.) | 263·2 | 137·5 | 78 | 54 |

From this it will be seen that there was a very striking decrease of exports as compared with the last normal year before the war. The greatest decline occurred in such groups as fish, canned goods, timber, wood-pulp and cellulose, paper and cardboard and unworked metals,—the most important articles of the country's export trade. As regards imports, industrial raw material showed a special decrease as compared with 1913.

The industries of Norway were organized into a national confedera-

tion in 1919, the Norwegian Industrial Confederation, after the dissolution in 1918 of an earlier (1886) union, the Norwegian Mutual Trade and Industry Association. The organ of the Confederation is the *Norwegian Industry*, which since 1919 has been published weekly in Christiania. Another organization for safeguarding industrial interests is found in the Norwegian Employers' Association, established in 1900. In 1921 it included about 2,200 undertakings, employing about 85,000 workmen. The administrative headquarters are at Christiania, and its organ is *The Employer*, which appears twice monthly in Christiania.

*Insurance.*—Private insurance work is carried out in Norway partly by mutual companies and partly by private joint-stock companies. During the war the number of companies, especially stock companies, as well as the amount insured, premiums, etc., increased very greatly. Prior to the war there were 25 joint-stock companies which carried out insurance against loss or damage; in 1915, 11 new companies were established, 12 in 1916, 27 in 1917, and 40 in 1918. The total number of insurance companies in 1921 was about 120, with a nominal share capital of 160,000,000 kr., of which half was paid up. There are 8 life insurance joint-stock companies, with a total capital of something over 6,000,000 kr. in addition to 3 mutual life insurance companies. Besides these companies there is the Norwegian Fire Office (*Brandkasse*), which has always taken the leading part as regards the insurance of houses and buildings. The companies which made the greatest progress during the war were those doing marine insurance, the number of which increased from 17 in 1913 to 77 in 1918. The total capital of Norwegian insurance companies at the end of 1920 was estimated to amount to about 500,000,000 kroner.

*Recent Political History.*—On the dissolution of the Union between Norway and Sweden in 1905 the internal party strife, which for a generation had exhausted the best energies of the country, ceased. It had been carried on between the Conservative party—chiefly an official party, which up to the severance of the union with Sweden sought to maintain this union so long as it could be carried out in a form in accordance with Norwegian national feeling—and the old Left, which still maintained its traditions dating from the 'eighties of the 19th century, when Johan Sverdrup (*see* 19.813) was all-powerful in Norway's domestic politics. The negotiations with Sweden under successive Governments had in 1905 reached a deadlock, and a crisis in the union presented itself at the same moment when the Norwegian parties were prepared to unite for common action. It was the fortune of Chr. Michelsen (b. 1857) to find this concord. With the liquidation of the union, and the consequent revision of the constitution as his sole programme, he formed in 1905 the so-called "7th of June Government," which practically had the whole Storthing and the whole of the people behind it. Meanwhile a new electoral party had entered into politics. From 1890 Labour had begun to separate itself from the Radical Left, and had formed the Social Democratic party, which subsequently increased in numbers and influence at succeeding elections, both in the Storthing and municipal councils. Although this party was not represented in the 1905 Government, it was nevertheless capable of forming a group which afterward had to be reckoned with. Simultaneously the new trade-union movement continued to progress, and gradually secured a separate influence in politics. On June 22 1906 the coronation of the new Norwegian King took place at Trondhjem, and thereby the mandate of the joint Government was consummated. The Storthing, however, continued its functions until a new National Assembly should be elected in the autumn. Chr. Michelsen personally opened the election campaign on June 26 with an address at Trondhjem outlining his programme. In it he recommended continued coöperation between the parties in order to "safeguard and consolidate the results of 1905." The Government programme involved the maintenance of the coalition, with a leaning towards the Left, and provided a basis for the "new labour day" which was now to be inaugurated. This standpoint so far secured the adhesion of the electors that there were elected 77 Liberals and Left of all shades, the majority being Coalitionists, while 36 Conservatives were elected who would only promise a conditional support to the Government, and 10 Socialists who stood in direct opposition to them. The position of the Government was therefore weakened after the meeting of the new Storthing, and its opponents combined themselves into a constantly more aggressive opposition. Attacks on the Government were notably strong during the spring session of the Storthing in 1907, when the question of establishing by law one of the "concessions" recommended by the Radical Left—for the purpose of conserving the natural resources of the country—came into the foreground.

In fact, the pivot of Norway's politics during 1906–12 was the so-called "Concession-case," *i.e.* the right of foreigners as well as of natives to hold, by Government concession, real property in Norway, especially waterfalls, mines and forests. This question came to the front during the second half of 1906, and in 1907 it gradually became obvious that it was about to cause a split in the majority *bloc*. However, this did not take place until after the withdrawal of Michelsen from public life in Oct. 1907, when the Cabinet was reconstructed by Jörgen Lövland (b. 1848), Minister for Foreign Affairs in the Michelsen Government. It was Mr. Lövland who negotiated the treaty guaranteeing the territoral integrity of Norway, signed on Nov. 2 1907, by Norway, France, Germany, Great Britain and Russia. One section of the large Government majority was in sympathy with the liberal "concession policy" of the Government, whereas the radical wing of the same majority claimed the issuing of laws that would limit the invasion of foreign capital. This conflict on one of the greatest problems of national economics finally led to a rupture, the result of which was the establishment of two different parties, the Radical or "Consolidated Left," and the "Liberal Left." In March 1908 Lövland's Cabinet, backed up by the Conservatives, and the Liberal Left, was driven to resign by the opposition of the Radicals and the Socialists. Gunnar Knudsen (b. 1848) formed a new Cabinet (March 18 1908). Besides being Premier he held the portfolio of the Minister of Finance. In his Government the radical Minister of Justice, Johan Castberg (b. 1862), attained great influence, especially as regards the elaboration of the new Concession Laws, which were passed in 1909. These laws, concerning (1) waterfalls, mines and other real property, and (2) forests, were sharply opposed by the Conservatives and the Liberal Left, as representing too severe an encroachment upon private property. In consequence of this opposition a reorganization of the Liberal party took place in March 1909, initiated by Chr. Michelsen, the former Premier. The coöperation between the reorganized Liberals and the Conservatives resulted in a new majority for these parties at the next general elections (Oct. 1909). This majority included 63 Conservatives and Liberals, as against 47 Radicals, 11 Socialists and 2 Independents.

In the meantime an old question of controversy between Norway and Sweden had been settled. From olden times the suzerainty over a certain group of submarine skerries (shelves) in the Kattegat, the *Grisebaaer* (Swedish: *Grisbadarne*), situated between the Norwegian group of islands, the *Hvaler*, and the Swedish islands of *Koster*, in the waters south of Fredrikshald, had been a matter of dispute between the two countries. The Grisebaaer, on account of the lobster fisheries in these waters, are not without a certain economic value. On March 14 1908 a convention was concluded between Norway and Sweden, by which the question of the right drawing of the border-line between these skerries was submitted to arbitration by the Hague Tribunal. The decree of the Tribunal, on Oct. 23, decided that the border-line be drawn in such a way that the Grisebaaer proper fell to Sweden, and a group of smaller submarine rocks, the so-called Skjöttegrunder, to Norway.

When the new Storthing met in Jan. 1910, Mr. Gunnar Knudsen tendered the resignation of his Ministry. It was with some difficulty that a new Government was formed, but finally, on Feb. 1 1910, the leader of the Liberals, Wollert Konow (from Fane, near Bergen, b. 1845), succeeded in constituting a Cabinet, consisting of Liberals and Conservatives, the former being preponderant within the Government, although the latter represented the majority in the Storthing. Women, having obtained in 1907 conditional rights of Parliamentary voting, were, in June 1910, granted by this Government the unrestricted Municipal vote. While the Konow Cabinet was in power a new Concessions Act and a new municipal taxation law were passed, both in 1911. In the same year, a new cable communication was established between Norway and Great Britain (Arendal–Newcastle).

The disproportionate representation of the parties in the

Government caused friction between the two allied groups and ultimately brought about a crisis resulting in the resignation of Konow and some of his Liberal colleagues (Feb. 1912). The Government was reconstructed by Jens Bratlie (b. 1856), with Conservatives as its chief element. Among the members of the Konow Government who passed into the Bratlie Cabinet was the Foreign Minister, Johannes Irgens (b. 1869), formerly Norwegian Minister in London, and after 1916 Minister in Copenhagen. When Mr. Bratlie became Premier he had to resign his seat in the Storthing and was replaced by the vice-deputy member,[1] Miss Anna Rogstad (b. 1854), who had been in the Storthing during the temporary absence of Mr. Bratlie in 1911. The case attracted general notice, as Miss Rogstad was the first woman representative in any independent National Assembly outside that of Finland, which admitted women in 1907.

At the general elections of 1912 a Radical wave swept the country, the final results being 76 Radicals, as against 24 Conservatives and Liberals and 23 Socialists. The Government, however, decided to remain in office till the Storthing met in Jan. 1913, when a new Cabinet was formed under the leadership of Gunnar Knudsen as Premier, with Niels Claus Ihlen (b. 1855; owner of a great foundry, and between 1908–10 Minister of Public Works) as Foreign Minister. This Cabinet remained in power until 1920.

Although the new Storthing, the outcome of the general elections of 1912, included no women, universal suffrage was extended to women in 1913. By an amendment of the constitution adopted in that year, Cabinet ministers were entitled to hold seats in the Storthing.

When war broke out in 1914 an extraordinary Storthing was called into session to decide upon the measures to be taken for the maintenance of the neutrality, or possibly for the defence, of the country. The sum of 10,000,000 kr. was voted for military purposes. A provisional moratorium was decided upon, and the right to redeem the Bank of Norway notes in gold was suspended for the time being. However, it was felt that the World War meant difficulties and dangers to each and all of the northern nations. The continual maintenance of neutrality was, to all of them, a matter of vital interest. Already on Aug. 1 1914, acting in coöperation, the authorities of the three countries passed resolutions binding the respective nations to take up and maintain an attitude of strict neutrality in the conflict between Austria-Hungary and Serbia. On Aug. 4 this declaration was repeated and extended so as to form a general rule of conduct during the war. On Aug. 8 a separate agreement was signed, in Christiania, on behalf of the Norwegian and Swedish Governments, embodying binding assurances from both sides, the purpose of which was to remove any possibility of either of the two kingdoms preparing hostile actions against the other.

The outcome of this desire for joint action in the political and diplomatic fields was a number of official meetings held during the war between the Monarchs, the Premiers and the Foreign Ministers of the Scandinavian countries. The first of these took place Dec. 18–19 1914, when, invited by the Swedish King, the two other Scandinavian Sovereigns met him at Malmo, where joint action was agreed upon in regard to solving a number of diplomatic questions, and questions appertaining to international law. In accordance with resolutions arrived at during this inaugural meeting, conferences were held in Copenhagen (March 9–11 1916), in Christiania (Sept. 19–20 1916), and in Stockholm (May 9–11 1917), where the Premiers and the Foreign Ministers of the three countries met. On Nov. 28–30 1917, the Kings of Sweden and Denmark paid an official visit to the Court of Christiania. King Haakon, on Sept. 16–18 1918, in Stockholm, returned the official visit of the King of Sweden. During June 26–28 of the same year, in continuance of the previous conferences of Scandinavian Cabinet ministers, a fresh meeting was held in Copenhagen. The last in this series of conferences took place in Stockholm (May 26–28 1919), in Christiania (Feb. 1–4 1920), and in Copenhagen (Aug. 28–30 1920). Besides these diplomatic and political conferences, a number of inter-Scandinavian meetings were held for the purpose of looking after common interests in the field of legislation, communication, commerce, administration and science. This new "Scandinavianism" differs essentially from the old ideological "University-Scandinavianism" of 1860. The adherents of the new movement acknowledge an absolute equality of rights in the relationship between the three nations, and presuppose a feeling of sympathy between these peoples, thrown upon each other through geographical propinquity, historical development and kindredship of race. The recognition of this fact gives rise in the three countries to a parallel "movement" for the purpose of organizing, in regular and permanent forms, inter-Scandinavian coöperation. The feeling grew steadily stronger that a similar organization would be of great import even in post-war times and on Feb. 24 1919 a great number of representative men in the three countries addressed the Public with an invitation to form a new society, the *Norden* (the North), having for its programme the defence of Right and Peace and common interests. The society has established a separate section and sub-sections for each of the three countries, having each their own management. The Norwegian section was founded on April 12 1919. A year-book is issued for the whole of the society. Its title is *Norden*. Two volumes, 1920 and 1921, have been published (Stockholm and Christiania).

A memorable year in the history of Norway was 1914, one hundred years having then elapsed since the country broke from Denmark to start as an independent state, sharing with Sweden, until 1905, her King and the administration of foreign affairs. The jubilee year was celebrated with a general Norwegian retrospective exhibition, at Christiania, embracing industry and fine arts. This exposition proved that in all fields of economic, industrial, technical and social activities, and not less in the spheres of intellectual life, science and art the country had progressed in a wonderful degree. Even financially the exhibition would have been a success, had it not been interrupted by the war.

The critical situation evoked by the outbreak of war in the industries of the country rendered emergency measures necessary in order to secure supplies, especially food-stuffs and coal. On Aug. 2 1914 a limitation was put on the amount of bread allowed to be sold, and mill owners suspended all orders. On Aug. 3 a panic set in, and the population of the towns stormed the shops to buy up goods. On Aug. 4 a Victualling Commission for the whole country was established. The task of this commission was to regulate the purchase from abroad of all the more important food-stuffs and necessaries of daily consumption, and to control their sale. On Aug. 5 a Royal decree was issued ordering the establishment of local victualling councils in all communes. The extraordinary Storthing which assembled on Aug. 8, however, helped to allay the feeling of panic, and a more tranquil condition came about by degrees. On Aug. 18 1914 war insurance for the Norwegian merchant fleet was established, and on Sept. 8 a private joint-stock company, the Norwegian Goods War Insurance Co., was instituted. At the close of Sept. the maximum prices already introduced for food-stuffs were provisionally abolished, except for certain kinds of bread. In place of them the Victualling Commission received authority to control prices and imports. This arrangement later involved a division of such administrative work, a Price Directorate being established in the following year to exercise control over the prices of all goods in retail trade. On Sept. 26 the Norwegian Government was authorized to take up a loan from Hambro & Son, London, of £600,000 (at 7% interest), so as to pay for two warships which were under construction for the Norwegian Government in English shipyards. These ships were, however, never delivered, since the British Government laid an embargo on them before their delivery. On Nov. 3 1914 England declared the whole of the North Sea to be a war zone, and Norwegian shipping was restricted to a small passage, Lindesnes–Farnesland; and on Nov. 5 the British Government stopped the passage N. of Scotland,

[1] In Norway every member of the Storthing had at that epoch a "vice-deputy member," elected in the same way and at the same time. This vice-deputy had to sit in the place of the actual member if he were prevented from attending through illness, etc., or if he were included in the Government. This way of substituting members of the Storthing was altered in 1920.

though permission was given for ships of the Norwegian-American Line, as from Nov. 7, to go that way. In 1915 and 1916 a considerable quantity of corn, meal, sugar, forage and fertilizing stuffs was bought in and contracted for by the Victualling Commission, which took over the whole trade in these articles. In 1915 a special commission was set up for dealing with the question of the national corn-supply in the event of the creation of a State monopoly. From 1916 all prices began to increase tremendously. The rise in prices kept pace with the ever-advancing increase in wages and salaries, and the pressure of high prices was rendered more acute by the high freights on all supplies from abroad. Thus from 1916 steadily increasing difficulties arose for most of the industries of the country, and the greater part of the population was affected, though an exception was found in the case of shipowners, whose profits were large. From March 8 1916, the Bank of Norway once again became obliged to redeem its bills with gold, but practically no advantage was taken of this, the population remaining passive as regards the facility of again obtaining gold. In 1916 it became necessary to introduce rationing of all the more important food-stuffs, especially all grain and meal products, meat, sugar, coffee and tea. The increasing difficulties of transport from abroad during 1917 rendered it necessary on Jan. 13 1918 to introduce a complete rationing of sugar, coffee, corn and meal goods. In the spring of 1919 the abolition of emergency regulations commenced, but it was carried out very slowly and with great caution, as all economic and social conditions had been deranged.

In June 1916 a heavy struggle in the labour market arose. It involved 120,000 industrial and transport workers and gave rise to some very frenzied demonstrations. On July 9 1916 the Storthing, as an urgent measure, and against Socialist protest, adopted a law compelling arbitration in industrial disputes. The last of the great labour conflicts of that time (mine-workers) was settled under the new Arbitration Law on July 22 1916.

The destruction of Norwegian merchant shipping by sinking and torpedoing commenced in the first days of the war, and increased steadily later until nearly the close of the war. In the autumn of 1916 even the Arctic Ocean became involved in the danger zone. Nevertheless, from the first day of the war till the last, Norwegian shipowners and seamen maintained their shipping on all the seas, though for a long time the heavy losses in ships could not nearly be replaced by new tonnage. The total loss of the country on the sea was 831 ships, of which 652 were steam or motor and 179 sailing ships, making a total of 1,238,300 registered tons. One thousand two hundred men were slain by torpedo or mine. These facts made a great impression in the Entente countries, and testimony hereto was provided by the presentation of a commemorative tablet for the Norwegian seamen lost through the war, which was placed on the masonry of the old fortress in Bergen. The memorial tablet was unveiled with great ceremony on Oct. 2 1921 by the vice-president of the Norwegian Club in London, Mr. Slingsby. The inscription reads: "To honour the memory of that great Company of free Norsemen, who, though at peace with all men, dared to defy the perils and horrors of War, and in rightful service endured fearlessly to the end, this monument is set up by their friends and admirers in Great Britain." (S. C. H.)

### Norwegian Literature

The first decade of the twentieth century was memorable in Norwegian literature for the passing away of the four great classics of the preceding epoch: Ibsen, Björnson, Lie and Kielland. After their death Knut Hamsun (b. 1857), Hans E. Kinck (b. 1865), Arne Garborg (b. 1851) and Gunnar Heiberg (b. 1857) became the leading literary figures, the first two chiefly as novelists, Garborg as a social and religious philosopher and poet, Heiberg chiefly as a dramatist and essayist. After the constitutional crisis of 1905, economic and social problems came to the forefront in Norwegian public life, and new ideas became prominent also in the field of fiction. There was a continuation, too, of the *maal* controversy (*see* 19.818), *i.e.* the effort to create an entirely independent Norwegian literary language based upon the peasant dialect (*landsmaal*), descended from the old Norse, in place of the Dano-Norwegian *rigsmaal*.

Hamsun had now become the most prominent representative of autobiographic fiction in Norwegian literature. His earlier productions in novels (especially *Victoria*, 1898), and particularly in his trilogy of dramas, *Rikets port* (1895), *Divets Spil* (1896) and *Aftenröde* (1898), were more especially occupied by the play and problems of eroticism, while his volume of verse, *Det Vilde Kor* (1904), contained emotional lyrics, including elegant poems of homage to Björnson and Byron. He then turned back again to self-absorbing psychological analysis in a series of narratives, *Under höststjernen* (1906), *Benoni* (1907), and *Rosa* (1908), which combine a curious bitter-sweet irony of life with cool epic presentation. These narratives formed a stepping-stone to his cycle of social romances, *Den siste glaede* (1912), a satire on tourist traffic which he denounces as demoralizing the Norwegian people, *Börn av tiden* (1913), *Segelfoss By* (1915), *Markens gröde* (1917), *Ny jord* (1918) and *Konerne ved vandposten* (1920). In these mature works, Hamsun has unrolled his picture of modern Norway; he here finds that industrialism has displaced agriculture, unhealthy speculation the honest, unassuming, but ethically invigorating toil of the day. Many of his books have been translated in England and America, such as *Growth of the Soil* (1920), *Pan* and *Mothwise* (1921; originally published in 1904 under the title of *Svärmere*). *Markens gröde* (*Growth of the Soil*) in 1920 secured him the Nobel prize. Hamsun's collected works have appeared in many editions, but the most complete is in the Jubilee Issue, published during the winter of 1921–2.

In Hans E. Kinck a strange, sombre, bitter and mocking romanticism is accompanied by a distinct strain of mystic horror. But no writer has excelled him in knowledge of the characteristics of the people of Norway. He himself grew up in Setesdalen and Hardanger, where tradition is still fresh and living. He displays his talents best in small peasant stories; one of his chief types is a man who is half dreamer, half horse-dealer. His series of romances, *Sneskavlen Brast* (1919), is remarkable for its weird realism. His dramas exhibit a fantasy which suggests the inspiration of Victor Hugo; *Den sisste gjaest* (1911) and *Mot Karneval* (1915) introduce Aretino and Machiavelli respectively, and his interest in historical personalities is also shown in the arresting essays *Reconnaissancemennesker* (1916). Kinck's profuse use of dialect words and self-coined expressions makes his works somewhat difficult even to his own countrymen; but he has found an inspired American interpreter and translator in Alfred E. Henderson, whose version of *Dr. Gabriel Jahr* was published in New York in 1921.

Arne Garborg had already written a cycle of lyrics in the *landsmaal*, *Haugtussa* (1895), which cleverly pictured a young peasant girl's natural emotions, her belief in subterranean and supernatural beings. In later years he showed his poetic ability in masterly translations into that tongue,—*Odysseuskvadet* (1918), a selection from the *Mahabharata* (1921), Holberg's classical comedy *Jeppe paa Berget* (1921). The last named was for presentation at a theatre established for the *landsmaal*, in the founding of which he took part together with his wife, Hulda Garborg (b. 1862), who has also written a volume of romance (*Frau Evas Dagbog*, 1905) and several plays. A jubilee edition of Arne Garborg's collected works, *Skrifter i samling*, was appearing in 1921–2.

Gunnar Heiberg has produced a series of effective dramatic works, mostly dealing with scenes in Norway. In a series of political and social plays, with relentless mockery, he pursues rhetoric when he encounters it,—the Björnson ethical imperative in *Kong Midas* (1890), nationalism in *Folkeraadet*, journalistic self-importance in *Harald Svan's mor*, philanthropy in *Kjaerlighet til naesten*, patriotism in *Jeg vil verge mit land* (a play on Norwegian politics at the dissolution of the union between Norway and Sweden in 1905), and, above all, with Aristophanic mockery in the comedy *Paradesengen*, which aroused a great sensation by aiming directly at Björnstjerne Björnson and his family. Some of his journalistic articles from Paris, where he resided for many years, were later collected in *Parisbreve* (1909),

*Set og hört* (1917), *Ibsen og Björnson paa scenen, Franske visiter, Norsk teater* (1920).

The realistic romance in vogue during 1870–80 retained some talented votaries in Norway, above all in Johan Bojer (b. 1872), who discusses modern problems in the romances *Liv* (1911), *Den Store Hunger* (1916), *Verdens Ansigt* (1917), *Dyrendal* (1919), *Samlede romaner og fortaellinger* (1917), and also in the plays *Troens magt* (1910) and *Sigurd Braa* (1916). Bojer's works are translated into English (*The Great Hunger, The Power of a Lie*), French and German; and a collection was published in America (Gade, *Johan Bojer, The Man and his Work*, New York, 1920). Nils Collett Vogt has continued the tradition of Wergeland and Björnson. For the centenary celebration he wrote an impressive cantata swelling with patriotism. His poetic collection *Hjemkomst* (1917) gives a beautiful expression of joy at returning home after many years' exile.

The more modern school of romance has two typical writers in Sigbjörn Obstfelder and Thomas P. Krag. Of these Obstfelder is the more piquant and original. His books were little noticed during his lifetime. His whole works only comprise two volumes (standard edition, 1921). All his writings are characterized by a peculiar artlessness, and the profundity of a solitary thinker. Thomas P. Krag (1868–1913) is better known. His stories have a delicate lyricism which lends them charm. In his religious romance *Gunvor Kjeld* he displays his first character-painting. His brother Wilhelm Krag has also displayed considerable productivity.

Of the younger lyric writers who came to the front during 1910–20, Herman Wildenvey, Olaf Bull and Arnulf Överland are the best known. Wildenvey (b.1886) heralds a new flowering in Norwegian lyrics. His graceful and captivating buoyancy secured him public favour from the outset (*Digte*, 1908). Olaf Bull's poems (*Samlede Digte*, 1919) are virile and reflective. Arnulf Överland is characterized by a strongly self-critical spirit.

Most of the newer Norwegian novelists have deserted "problems" for realistic delineation. Peter Egge (b. 1869) began with pictures of folk-life in the form of narratives, *Nordfra, Tröndere, De graa haar*, and plays, *Faddergaven* and *Jakob og Kristoffer*. From these pictures of folk-life he went on to romance in *Hjerter* (his chief book, 1907), *Laenken, Villaen, Unge dage*, and the witty comedy *Kjærlighet og venskap*. Later plays are *Felen, Idyllen, Brist* and *Narren*, soul-dramas recalling Ibsen.

Tryggve Andersen (1867–1920) is a narrator of high rank. His first book, *I cancelliraaden dage* (1897), was a series of lively interiors from the broad country of Mjösen at the commencement of the 19th century. His second, *Mot kvæld* (1900), deals with the last struggle of a poor and homeless soul-sick man to attain the balance and substance of life. His stories *Gamle folk* (1904), *Bispesönnen* (1907) and *Hjemfærd* (1913), with other writings, are collected in *Samlede fortællinger* (3 vols. 1916).

Kristian Elster, the younger (b. 1881), is a writer of a different style, but a robust artist. His best work is in the three consecutive narratives *Ilaere, Landeveien* and *Mester*, which give expression to his warm sympathy with the poor and oppressed. His critical essays are collected in *Fra tid til anden* (1920).

The popular humorist Jacob Hilditch maintained his reputation during later years, the best of his work being collected in *Sjöfortallinger* (1906) and *Fortællinger fra folklivet* (1908).

Hjalmar Christensen (b. 1869) has produced a series of narratives, *Fra Vestlandet, Fögedgaarden* (1911), *Brodrene* (1912), *En gamle bygd* (1913), *Den nye bygd* (1914), *Far og sön* (1915), *Et liv* (1916), *Tuntræet* (1917), *Deemring* (1918), which are collected in *Samlede Romaner* (1920). Together with F. E. Christensen (b. 1872) he also wrote *Fædrelandet i verdenskrigen lys* (1916), a frank historico-political account of Norway's position in the World War.

Among the younger generation an outstanding figure is Johan Falkberger (b. 1879), a mine-worker who became editor of a Socialist paper, in which he wrote many sketches from the lives of the workers. He then produced in rapid succession a series of narratives, *Svarte Fjelde* (1907), *Urtidsnat* (1909), *Fakkelbrand* (1909), *Eli Sjursdotter* (1913). His *Lisbet paa Jarnfjeld* (1915) is remarkable for its power and pathos. Oskar Braaten (b. 1881) in like manner worked himself up from a lower station, and his subject is the working population of the suburbs of Christiania; he writes in a popular language of East-lands colouring, resembling the *landsmaal*.

Gabriel Scott (b. at Leith, Scotland, 1874), who had already made his *début* at the close of the 19th century, came to the front again with his comedy *Himmeluret* (1905), an excellent piece of psychology in *Camilla Dyring* (1906), and the witty *Babels Taarn* (1910), depicting the struggle between the *landsmaal* and the *rigsmaal*. *Det Flyvende Börd* (1906) is a story of adventure; and the romances *Jernbyrden, Enok Rubens Levnedslöb* and *Kilden* deal with life in olden times on the coast of southern Norway.

The gifted authoress Ragnhild Jölsen (1875–1908), in her narratives *Ve's Mör, Rikka Gan, Fernanda Mona, Brukshistorier, Hollasas Krönikel*, has left some characteristic pictures of the Norwegian eastern countryside. And among the women writers who have followed her the most important is Sigrid Undset, whose stories and romances have been collected in five volumes (1921).

As a wit and satirist, Nils Kjær (b. 1870) has taken a leading place, notably through his dramas *Regnskapets Dag*, and *Det Lykkelige Valg*. A complete edition of Kjær's dramatic and critical works was being issued in 1921–2. Sigurd Mathiesen (b. 1871), whose earlier stories *Unge sjæle, Hide Unas* and *Nag* were followed in 1919 by the romance *Francis Rose*, showed himself to be a true poet in his collected verse, *Gjennem aarene*.

The cosmopolitanly inclined Seblein Lieblein (b. 1866), son of the famous Egyptologist, J. D. C. Lieblein (1827–1911), has written a number of entertaining stories, notably *Den sisste av sin slegt* (1910) and *Peter Flytt's haendelser*. Another author international in thought and choice of material is Eilert Bjerke (b. 1887), among whose works are the novels *Mennesker og fauner* (1909), *Fri Fugle* (1910), *Meteorer* (1918), *Livsfyrsten* (1914) and *Sværmere i Solen* (1917).

Sigurd Wesley Christiansen (b. 1891), beginning with *Seiren* (1915) and *Thomas Hergel* (1917), proved his talent for fiction by *Vort Eget Liv* (1918), and for drama by *Offerdöden* (1918). Ronald Fangen (b. 1896) likewise in 1915 produced his first romance *De Svake*, following it with *Slegt föder slegt* (1916) and *En Roman* (1918). His essays, *Streiftog i digtning og taenkning* (1919), show him also to be a subtle critic of literature. In 1921 his first play, *Syndefald*, was produced at the National theatre in Christiania.

Jens Tvedt ranks highest among the *landsmaal* writers, with his sketches of western Norway country life. Among other writers in *landsmaal* Olav Dunn (b. 1876) takes a leading place with his romances *Paa Lyngsoia, Juvikingarne*, and *I Blinda*. The chief lyricist of the *landsmaal* is Anders Hovden (b. 1860), and the younger generation is well represented by Kristoffer Uppdal (b. 1878).

(S. C. H.)

**NOSKE, GUSTAV** (1868– ), German Socialist leader and former Republican Minister of National Defence, was born July 9 1868 at Brandenburg. He was by occupation a worker in wood, but took to writing for Social Democratic newspapers, and was from 1897 to 1902 on the staff of the *Königsberger Volkszeitung* and afterwards on that of the *Volksstimme* at Chemnitz. At the end of the latter year he returned to Brandenburg, where he was elected a member of the municipal council and in 1906 a member of the Reichstag. Throughout the World War he belonged to the Governmental section of the Socialists, and voted in the Reichstag for the war credits. When in the first week of Nov. 1918 the mutiny, which had broken out in the navy at Kiel, developed into sanguinary street fighting and the naval authorities were unable to restore order, Noske was sent to Kiel with the Democratic Secretary of State, Hausmann, and, after a conference with representatives of the sailors and dockyard workers, arranged a suspension of hostilities on the basis of the sailors', soldiers' and workmen's demands. This triumph of the mutiny was the beginning of the German revolution, and the sailors from Kiel and other northern ports carried the idea of Workmen's and Soldiers' Councils throughout the north of Germany and ultimately to Berlin. Noske was appointed governor of Kiel, where he remained until he was recalled on Feb. 11 1919 to assume the office of Minister of National Defence (*Reichswehrminister*) and to organize military forces for the suppression of the Communist insurrections in the capital. In his book *Von Kiel bis Kapp* (1920) he gives an account of the difficulties which he encountered in getting together an efficient army for home defence. He had to accept the services of many ex-officers whose hearts were with the old régime, and he also found it difficult and, in some cases impossible, to dissolve reactionary Free Corps like those which returned from the Baltic provinces or like Ehrhardt's Marine Brigade. His dependence upon troops and leaders of this character facilitated the military insurrection under Gen. von Lüttwitz which supported the Kapp *coup* of March 13 1920. Noske appealed in vain to the troops in Berlin to resist the occupation of the capital by the forces which Lüttwitz led from the camp at Döberitz. He was one of those ministers who, with President Ebert and Chancellor Bauer, fled from Berlin to Dresden, and afterwards to Stuttgart. After the suppression of the Kapp troubles and the return of the Ministry to Berlin it was impossible for Noske to remain in office, as the labour masses, who by the general strike against the Kapp "Government" had for the moment obtained a decisive influence upon affairs, regarded him as having been too tolerant of reaction in the army and as having manifested excessive ruthlessness in the suppression of the Communist bands. Noske, notwithstanding the genuineness of his Republican and Social Democratic opinions, enjoyed con-

siderable popularity in the new army and with the reactionary friends of law and order, as a man of decided character, great energy and resourcefulness in times of crisis.

**NOVA SCOTIA** (*see* 19.830).—The pop. of this Canadian province increased from 459,574 in 1901 to 519,000 in 1911, including 122,084 in Cape Breton, representing an average density of 24·2 to the sq. mile. During the decade 1911–20 the growth of industry in towns like Sydney tended to compensate for the loss of rural population by emigration to the eastern States and to the Canadian N.W., which has largely ceased. About 80% of the pop. are of British descent. The chief towns of Nova Scotia, with their pop. in 1911 and 1920, are as follows:—

| | 1911 | 1920 |
|---|---|---|
| Halifax (capital) | 46,619 | 65,000 |
| Sydney | 17,723 | 21,400 |
| Glace Bay | 16,562 | 18,600 |
| Amherst | 8,973 | 9,250 |
| Sydney Mines | 7,470 | 8,700 |
| New Glasgow | 6,383 | 7,400 |
| Truro | 6,107 | 7,600 |
| Yarmouth | 6,000 | 6,600 |
| Springhill | 5,713 | 6,400 |
| North Sydney | 5,418 | 6,780 |
| Dartmouth | 5,058 | 6,400 |

The Legislative Council of Nova Scotia consists of 21 members appointed by the Executive Council of the province, a Legislative Assembly of 43 members elected by the people, and an Executive Council of eight members chosen from the Legislative Assembly and the Legislative Council. The province is represented in the Dominion Parliament by 16 members of the House of Commons and 10 Senators. The revenue is chiefly made up of the Dominion subsidy and of royalties on mining concessions, chiefly those on coal. As a consequence the direct taxation which the people of Nova Scotia have to pay is very small, and is limited to the local rates which they levy on themselves for municipal and school purposes.

Each county has its high school or academy, and there are several universities. The province supports a normal school and agricultural and horticultural schools at Truro. Dalhousie College and University at Halifax is undenominational. Halifax has also a school for the blind and an institution for the deaf, and is the seat of a Presbyterian theological college. The universities of King's College at Windsor, Acadia College at Wolfville, and St. Francis Xavier at Antigonish are under the jurisdiction of the Anglicans, the Baptists, and the Roman Catholics respectively. A technical college maintained by the Provincial Government is in operation at Halifax, and technical night-schools are conducted in every industrial town in the province. The Executive Council is the supreme governing body and acts with the superintendent of education. It appoints a board of examiners for teachers and a staff of school inspectors. The province is divided into school districts, for each of which a board of school commissioners is appointed by the Government. The districts are subdivided by the commissioners into school sections, and these are administered by a board of three trustees elected by the ratepayers. The schools are supported by Legislative grants, supplemented by a statutory municipal taxation. In 1918 there were 2,859 schools, 3,037 teachers, 108,094 pupils; the total expenditure on education was $1,818,155, having doubled in 15 years.

*Agriculture* was in 1921 the leading industry of Nova Scotia, the annual production exceeding $27,000,000. The value of field crops for 1919 was over $22,000,000, or about $11,000,000 more than in 1915. There is abundance of fertile land in Nova Scotia for general farming, and especially for the small holdings which should supply the needs of the larger towns, the manufacturing and mining centres, and the summer visitors. Hay and cereals are largely grown, and all root crops in the province are heavy. Rich soils abound in the 700 sq. m. of the Annapolis and Cornwallis valleys, of which one-tenth is planted; also in dyke lands and in a network of intervals. From the wild clover pasturage comes the finest Canadian wool. The produce is marketed in Canada and the West Indies, on the U.S. seaboard and overseas. The 50,000 ac. of dyke marshlands reclaimed from the sea, lying mainly at the head of the Bay of Fundy, have for a century or more produced crops of hay up to 3 tons per acre. Their continued fertility is due to the rich mud brought in by the tide and either deposited on the land by flooding or spread on the higher level. In the seven northern counties, including Cape Breton Island, conditions of soil, climate and topography have resulted in a greater proportion of good land, and, therefore, of wider clearings, than on the Atlantic slope. In the southern and western counties one of the most fertile intervals is that of the Musquodoboit river, the upper branches of which run through a limestone formation. This valley has been opened up by a recent 80-m. extension of the Canadian National railways to a point 40 m. E. of Halifax. In the slate formation also there are rich intervals such as the Tusket valley between Kentville and the sea, and the valley of the Lower Sissiboo. As a rule, the cultivated lands in these counties lie along the seaboard, for the interior granite areas do not invite settlement. The Annapolis and Cornwallis valleys are notable for their apples, several varieties of which are the best in the world and find a large market in Great Britain. Peaches, pears, plums and cherries are also grown. Dairying also has become an important industry; about $950,000 worth of creamery butter is produced annually. Travelling dairy schools supported by the Provincial Government visit all parts of the province to give instructions to the farmers. The Provincial Government has also established 35 model orchards throughout the province. Agricultural education receives stimulus not only from the Government but from various agricultural societies.

*Lumber.*—It was estimated that in 1920 the province had about 12,000 sq. m. of good timber land, all privately owned, but well looked after by a thorough system of fire protection. A large export trade is carried on with Great Britain, the United States, the West Indies and South America. The value of the lumber cut in 1918 was $4,092,039. Eight pulp mills were in operation in 1920 the output of which was valued at $243,451.

*Fisheries.*—The fisheries of Nova Scotia are next to those of British Columbia, the most important in Canada, and the value of their products was $9,166,851 in 1915 and $15,171,929 in 1919. The value of fishing boats, vessels, nets and other materials amounted to over $16,000,000. The catch was greatly stimulated by war demands for cheaper food. The total number of men employed is about 26,000; the vessels are manned with about 9,500 men and another 16,000 are employed in curing, canneries and allied industries.

*Mining.*—The annual production of bituminous coal amounts to about 6,000,000 tons, chiefly from Cape Breton, the N.E. portion of the province. The mines in Cape Breton county yielded 3,992,733 tons in 1920 out of a total for Cape Breton of 4,237,065 and for Nova Scotia of 5,087,744. In that year the province consumed 2,445,195 tons and 896,404 tons were exported to New Brunswick, 297,434 tons to Newfoundland, 240,701 tons to Quebec, 527,727 to Europe and bunkering accounted for 485,609 tons. The exports to the United States, which amounted to 532,684 tons in 1915, had sunk to 27,439 tons in 1920. Iron and copper are found but not largely produced, the chief supply of the best iron ore for blast furnaces coming from Newfoundland. Of the 20 blast furnaces in operation in Canada 8 belong to Nova Scotia. These have a capacity from 250 to 350 tons per day each. The average yearly output of gold for 50 years has been $200,000, the highest in any one year being $400,000. In 1919 850 oz. were produced, valued at $19,130. A valuable deposit of rock shale discovered under a farm near Malagash, Cumberland county, may prove of great importance to the Maritime Provinces, where the fishing industry alone consumes 50,000 tons a year. The amount of deposit here is estimated at millions of tons, and some of the samples have shown high percentages of potassium salts. The strata in Nova Scotia are said not to be favourable for oil or gas, but in Pictou county there is an area of about 10 sq. m. of oil shales. Antigonish and Colchester also contain valuable areas of oil shales. The report of the fuel controller for Canada estimated that these shales will yield 400,000,000 bar. of oil and 7,000,000 tons of ammonium sulphate.

*Commerce and Manufactures.*—The shipbuilding industry has shown a strong forward tendency. In 1916, 60 wooden vessels representing 12,000 tons were completed, and the war stimulated the yards to such full and effective work that, in 1917, 20,000 tons were completed without any Government aid to the builders. The war demands for shipping proved the possibility of building steel ships in Canada, and an arrangement was made with the Dominion Iron & Steel Co. of Sydney by which the latter undertook to build the first plant in Canada capable of producing heavy plates. At Halifax and Dartmouth a modern shipbuilding yard was at work in 1921. The Halifax Shipyards, Ltd., took over the existing repair plant and dry-dock at Halifax and the marine railways at Dartmouth, and undertook to provide for building ships up to 12,000 tons.

The manufactures of the province include sugar refineries, textile and boot and shoe factories, pulp and paper mills, canneries, iron works, machine and agricultural implement shops, and iron furnaces. The principal manufacturing centres are Halifax, Sydney, New Glasgow and Amherst.

The value of Nova Scotia's production for 1919 was estimated at $192,197,300, of which coal contributed $25,000,000, iron and steel products $19,000,000, fisheries $14,350,000, manufactures, ships and freights $56,260,000, products of the farm $51,034,000, products of the forests $16,965,000.

*Roads and Railways.*—Nova Scotia is sharing in the general movement towards the construction of good roads. Roadmaking machines are employed for the improvement of the ordinary highways and

steel bridges have replaced the wooden structures. The Canadian National Railways, formerly the Intercolonial, is the chief means of communication with the other provinces and for the carriage of local traffic. Halifax is connected by that line with Windsor and Truro at the heads of the two great arms of the Bay of Fundy. The same line connects with Pictou and Sydney, Cape Breton, and in passing over the isthmus, to connect with the main Canadian system, the line traverses the Cumberland mining district. There is a line of railway from Halifax to Chester, Lunenburg, Shelburne and Yarmouth; also from Truro to Windsor and down the Annapolis valley to Digby and Yarmouth, and a branch connects the valley with the Atlantic coast at Lunenburg. There is a spur from the Springhill coal-mines to Parrsboro, their shipping port, on the Basin of Minas. One connecting Oxford Junction with Pugwash, River John and Pictou, another connecting the Cape Breton coal-mines with Sydney and Louisburg. The Joggins coal-mines are reached by a spur of the Intercolonial railway from Maccan near Amherst. The C.P.R. has running rights over the Government system from St. John, N.B., to Halifax and similar rights are granted to the National Transcontinental from Moncton to Halifax. Halifax is in communication with Europe by several lines of steamship. There is also a line to New York and one to Boston and lines of coasting steamers run to Canso and ports in the Gulf round the coast westwards. Steamers also ply regularly to St. Johns, Newfoundland and Sydney. The Atlantic cable stations are at Canso and Sydney. The Canadian Government radio-telegraph stations are at Glace Bay (trans-Atlantic only), North Sydney, Pictou, Camperdown (Halifax), Cape Sable, Barrington and Sable Island. (W. L. G.*)

**NOVELLI, ERMETE** (1851–1919), Italian actor and playwright (*see* 19.838), died at Naples Jan. 29 1919. His tragedy *La Masque*, written in collaboration with Signor Bonaspetti, was produced in 1911.

**NOYES, ALFRED** (1880– ), English poet, was born in Staffs., Sept. 16 1880. He was educated at Exeter College, Oxford. His first volume of poems, *The Loom of Years*, appeared in 1902, and his *Collected Poems* in 1910. His *Forty Singing Seamen* (1907) and *Drake* (1908) were characteristic of his patriotic note as a poet of the sea. During the World War he did work for the English Foreign Office. A volume of lectures given in America, *The Sea in English Poetry*, was published in 1913, and in 1914 he was elected to a professorship of modern English literature at Princeton University. During the war he published *The Wine Press* (1914); *A Salute from the Fleet* (1915); *Rada*, a play (1915); and a volume of stories, *Walking Shadows* (1917). In 1920 he issued a new volume of poems, *The Elfin Artist*.

**NOYON, BATTLE OF.**—The battle of Noyon, in the course of the last German offensive on the western front, was fought on June 9–13 1918.

The operative situation of the Germans between the Oise and the Marne was at that time as follows. The new wedge-like German positions, won in the battle of Soissons-Reims, and pushed southwards, afforded favourable targets for hostile attacks with their deep flanks at Reims and opposite the wooded heights of Reims, and also S.W. of Soissons and opposite the wooded district of Villers-Cotterêts. Strategically, therefore, it was desirable to bring the German positions on both sides of the Oise into the general line Montdidier–Château-Thierry, at least on the right wing, by the capture of the wooded heights between the Oise and the Aisne and N. of Villers-Cotterêts, thus improving the strategic situation on the front between the Marne and the Oise. The capture of Reims and its wooded heights also became a more pressing operative necessity on account of the difficulties of bringing up supplies to the troops standing on the Marne.

From the operative point of view it would have been desirable for the XVIII. Army to have advanced to the attack simultaneously with the VII. Army, but this had not been possible on account of the want of sufficient material for the attack. The attack of the XVIII. Army could be carried out only in succession to that made by the VII. Army; it was to be delivered from the front Montdidier–Noyon with the right wing against Méry, with the middle and left wing against the very strong positions on the heights W. of the Oise, and to be supported by a simultaneous attack by the VII. Army from the country S.W. of Soissons, and in this way to compel the French to give up their positions between the Oise and the Aisne. The attack, commencement of which was originally fixed for June 7, had to be put off to June 9, as the artillery preparations could not be finished in time. This was the more disadvantageous as the French (to whom, as appeared later, the whole undertaking in all its details had been betrayed some days earlier by deserters) gained time, by bringing up and placing sufficient reserves, to prepare themselves for the attack and to disturb the German preparations by systematic artillery fire.

Of the XVIII. Army the IX., XVII. and VIII. Army Corps and the XXXVIII. Res. Corps, with a total of 18 attacking divisions, were to take part in the attack. The IX. Corps, standing on the right wing of the attacking troops, was on its part to maintain the connexion with the III. Army Corps and its own old positions, while the XXXVIII. Res. Corps advancing on the left wing was to advance first along the Oise and later to attempt to cross the river in an easterly direction. The fighting task of the centre corps, the XVII. and VIII. Army Corps, was a determined push straight against the enemy. In spite of the hindrance caused by the French artillery fire the preparations for the attack were successfully completed on the evening of the 8th. The attack itself began in the early morning of the 9th.

The German artillery preparation was on this occasion also fixed for the night hours. The French response, in consequence of their expectation of the German attack, was considerable over the whole front, stronger than at the attack on the Chemin des Dames. At 4:20 A.M. the infantry advanced to the attack. They met with stiff resistance, especially on the right German wing, where the French had brought up strong reserves. In spite of the prevailing thick mist and the impossibility of observation in the forest country, which made the disposition and leading of the infantry very much more difficult, the whole French system was successfully penetrated in the course of the day and progress made beyond it. On the right wing the IX. Corps on the evening of the 9th retained the village of Rubecourt, temporarily lost, in spite of the most violent French counter-attacks. The two centre corps had reached the line Courcelles–Cuvilly–Mareuil, while the XXXVIII. Res. Corps had established itself in possession of the woods S. of Orval. June 10 saw a remarkable success on the left German wing, due to the wheeling-in of sections of the VIII. Corps against the flank of the French troops standing opposite the XVIII. Corps, which opened up for this corps the advance to Cambronne and Ribécourt. Weak sections of this corps pushed forward from here eastwards over the Oise, while the two centre corps, after the capture of Marquéglise, pushed forward to both sides of Antheuil. Under the pressure of the attack of the left wing of the XVIII. Army, the French in the night of June 10–11 evacuated the woods of Carlepont before the right wing of the VII. Army.

The right wing of the XVIII. Army fought fiercely on June 10 at Courcelles and Méry without being able to make further progress, as the French had more and more made this front the centre of their resistance.

The course of the German attack up to this point, and the information of airmen and prisoners, had shown that the opposing army had placed very strong reserves in readiness before the German right wing, and that further advance was to be achieved only with extreme loss of life and by the throwing-in of strong reserves. The German Supreme Command, therefore, determined to content itself with the successes achieved, and to break off further fighting, especially as on the morning of the 11th on the right wing, heavy French counter-attacks, with the support of strong artillery and numerous tanks, had begun against the front Courcelles–Méry–Belloy. In front of Courcelles they were shattered indeed; but between Méry and Belloy the French had scored transient successes; both places were lost and the French had pressed forward in the direction of Cuvilly; a German counter-thrust undertaken with fresh reserves repulsed them towards evening as far as the eastern edge of Méry.

The Supreme Army Command on the 11th ordered the German right wing to suspend the attack and to restrict itself to the defensive. On the next day this order was extended to

the whole front of the XVIII. Army. All the repeated French attacks, made with great masses and supported by strong artillery preparations and tanks, were repulsed before the front of the XVIII. Army with heavy losses. The Germans retained the positions captured during the engagements of the 9th and 10th on the general line of the heights S.W. of Montdidier–Courcelles–Antheuil–northern bank of the Matzbrook.

The German attack undertaken from the district S.W. of Soissons by the VII. Army to relieve the pressure on the XVIII. Army had led to no substantial successes. The flanking artillery fire falling behind the lines and on the French forces fighting E. of the Oise had indeed inflicted severe losses; but the French had placed such strong reserves in readiness on this front that the German attack undertaken between the southern slopes of the Aisne and the forest of Villers-Cotterêts had been able to make substantial progress only in the centre and to penetrate into the north-eastern section of the forest of Villers-Cotterêts. It was, however, clear on the 12th that the attack begun here would not penetrate farther; very violent Franco-American counter-attacks began on this day, especially opposite the VII. Army and particularly at Château-Thierry and W. of the wooded heights of Reims.

In the battle of Noyon the Germans took 15,000 prisoners and 150 guns; but the engagements between June 9 and 13 had not substantially altered the German strategic situation on this section of the front between Soissons and the woods of Villers-Cotterêts. (H. v. H.)

**NURSING** (*see* 19.914)—UNITED KINGDOM.—The modern nursing movement has developed from the introduction of a new type of woman. One of the principal points of Florence Nightingale's organization (*see* 19.684) was that the hospital matron should have complete authority in regard to her own sphere and not be under the direction of the male hospital staff in regard to the training and management of the nurses, and this is now the recognized English system under whose influence the movement for educated nurses has during the last 50 years proceeded apace. Thus nursing has gradually become a fully organized profession. Hospital work is now divided into many sections, and in large training schools not only are there nurses performing administrative work alone, but nurse instructors and tutors form part of the staff. There are likewise specialists in electric and other technical work, but these (and also those who take fever and other special trainings) are often postgraduates, while, on the other hand, young women sometimes nurse in children's hospitals as well as in cottage and convalescent hospitals before they are old enough to begin their regular training. The age for commencing training in recognized training schools (which are roughly those having over 100 beds and a resident medical officer) used often to be 25, but in many hospitals it has been reduced to 21 since there is difficulty in getting older probationers. The length of training varies from three to four years, and examinations are held at stated intervals. The nurses usually occupy a nurses' home within the precincts of the hospital, though there has been a movement towards allowing at least some of the staff to live out. The "sister" probably retires at 50 or 55, and a pension is frequently provided, with or without contribution. Postgraduate teaching is developed in the best schools.

*District Nurses.*—If a nurse in England wishes to take up district work on completing her training she may have her district training and be placed on the roll of the Queen's Nurses (established to commemorate the Jubilee of Queen Victoria), a body which has done much to ameliorate the lot of the sick poor in the United Kingdom. These nurses are supported and controlled locally but supervised from headquarters where they are trained, and a high standard of efficiency is maintained. In Ireland a special fund was raised to assist in the support of these nurses. Another type of nurse is named the "Cottage Nurse." These district nurses only receive a short training, usually under what is called the "Holt-Ockley" scheme, and the idea is that they should reside in the houses of their patients and be somewhat of their class. It is considered advisable that district nurses should hold the certificate of the Central Midwives' Board, more especially as these nurses are frequently employed in infant and child welfare work.

*Public Health Nurses.*—Public health nursing has developed largely since 1910. Child welfare work is only one of these developments. In Great Britain a large number of nurses are employed under the county, borough or city schemes for this work and also for tuberculosis visiting. Then education authorities require a large staff for following up the cases of children who have been inspected under their health schemes. There are also nurses in connexion with industrial welfare work. Fever and isolation hospitals supply another form of public nursing work. This form of nursing is sometimes undertaken after graduation, and sometimes the probationer takes her fever training before going on to work in a general hospital. The full course of fever training is usually three years.

There are many large Poor Law infirmaries which give excellent training and are recognized as training schools. The advantage claimed for them over hospitals which are also training schools for the medical profession is that at present, being without students, there is more left for the nurses to do. On the other hand there is a large number of chronic cases, and the number of patients per nurse which in general hospitals may be three is in Poor Law infirmaries much larger. The nursing in small infirmaries (called Poor-house or Parish hospitals in Scotland) is done by a superintendent with nurses under her. In the case of there being a single nurse she may be placed under an untrained matron or governor, and this has been the source of complaint. The nursing of the sick poor has greatly improved, but various further recommendations were made by the Royal Commission on the Poor Law (appointed 1905) which involve changes in administration.

*Private Nurses.*—Private nursing in England has expanded enormously during recent years, and though there are some "visiting nurses" who come in for the day they are mainly residential. The nurses who undertake this kind of work are to be had either from a hospital which sends out its nurses after they gain their certificate and allows them to return to the wards when free, or from an Institution or Home. There are very few independent nurses working by themselves, but many belong to a "Coöperation," to the headquarters of which the nurse returns after her case is completed, and to which she contributes a percentage of her earnings. There are many private nursing homes for the well-to-do where nurses are employed. The qualifications of these nurses vary according to the quality of the home.

*Mental Nurses.*—The training for mental nursing is usually conducted in a recognized institution for the treatment of mental disorders, where the candidates serve for three years. At the end of this time they may obtain the certificate of the Medico-Psychological Association. The nurses and attendants are of both sexes, but though male patients are usually nursed by male nurses, women are being increasingly made use of even for men, more especially in Scotland, where what is called the "Hospitalization" of institutions for the mentally affected is becoming common. It is claimed that the result of employing women (with some male assistance) has been proved to be very satisfactory. When the nurses in training have already taken their certificate in a general hospital they are allowed to enter for their examination at the end of two years instead of three, and are exempt from the examinations at the end of the first and second years. The training is very thorough, and a careful register is kept of those who qualify and in case of misdemeanour the name is erased.

*Masseurs and Masseuses.*—There is a Chartered Society of Massage and Medical Gymnastics (amalgamating the Incorporated Society of Trained Masseuses and the Institute of Massage and Remedial Gymnastics) which grants a diploma to those who have taken their preparatory course at a recognized school or hospital, or who have passed an examination. Soon examination in massage alone will cease, and candidates will be required to sit for a conjoint examination in massage and medical gymnastics, after scheduled training under recognized teachers.

*Midwives and Maternity Nurses.*—Midwifery is controlled by a Central Midwives' Board established in London and having jurisdiction in England and Wales. There are separate Boards for Scotland and Ireland. The number of midwives now appearing on the Roll in England and Wales is approximately 48,600. This Board, which was established under the Midwives Acts of 1902 and 1918, submitted certain rules to the Privy Council, which were approved by them. Its business is to regulate the issue of certificates and the conditions of admission to the Roll of Midwives, as also to regulate the course of training and the conduct of examination. It has likewise the power to remove a name from the roll, or restore a name removed. In addition it gives directions to midwives in their work.

Though the Act came into operation in 1905 it was only after 1910 that it was forbidden to attend women in childbirth for gain otherwise than under the direction of a qualified medical practitioner, unless certified under the Acts. Certification depends on compliance with the rules and regulations laid down in pursuance of the Act. The midwife acts under the local supervising authority. The number of midwives has of course increased largely; but still demand exceeds supply, as their emoluments are not sufficiently large to make the work of district midwife attractive unless supplemented by public or private funds. There is an incorporated midwives' institute which has been useful in promoting the interests of midwives. A large number of trained nurses take the certificate after training and work as "Queen's" district nurses or otherwise. Other qualified midwives have a short general training. These die

also maternity or monthly nurses who can be engaged, as required, by members of the more opulent classes, and they frequently have a midwifery training as well as some general training; but their qualifications vary.

*Nursing Organisation.*—As regards the organization of nurses, the British Nurses' Association was set on foot under the presidency of Princess Christian in 1888. The goal of the advanced party was to establish a minimum of training, and to do this through a central governing body appointed by the State and thus to prevent untrained women claiming the position of trained. Those who opposed the view asserted that in the nursing world efficiency could not be tested by examination nor its continuance guaranteed. The Association obtained a Royal Charter in 1892. But serious dissension soon arose, which emanated from those who were strongest in affirming the necessity of the registration being carried on by the State, for at first the British Nurses' Association was content with advocating a voluntary register. In 1894 a Matrons' Council of Great Britain and Ireland was set on foot by the advanced party, and in 1902 a Society for the State Registration of Trained Nurses was established. A bill for State registration was introduced into the House of Commons in 1903, and another the following year. As there was strong opposition to the project a select committee of the House of Commons was appointed to investigate it, and its findings were more or less favourable to the scheme. After it reported in 1905 the warfare continued with extreme vehemence (on the registration side later on with the help of a central committee founded 1910) until the outbreak of war, when a truce was declared. In the year 1916 a College of Nursing was established which was designed to form a centre for all nursing activities and to direct nursing education on proper lines. It has branches throughout the United Kingdom, and in 1921 had 20,000 members. The College supported a scheme for registration somewhat different from that of the central committee, and as it proved impossible to obtain agreement the long struggle over registration was brought to an end by the Minister of Health deciding that the Government would bring forward its own bill. This was done, and the Nurses' Registration Act became law in the end of 1919.

The nursing profession, after a long time of controversy, was thus in 1921 entering into a new phase in which it had obtained powers of self-government. It had already through its organization claimed and secured a considerable increase in pay and decrease in hours of duty;[1] but it considers that there is much work before it, if wholly satisfactory conditions are to be obtained. It is estimated that there are about 40,000 fully trained nurses in the United Kingdom, although there may be double that number eligible for State registration during the period of grace. The Act of 1919 establishes a General Nursing Council for England and Wales and another for Scotland. Of the 25 members of the English Council 16 must be registered nurses elected by persons registered under the Act. It provides for three supplementary registers (for male, mental and sick children's nurses) as well as the general register, and it regulates the admission to and removal of names from the register, as well as the training of registered nurses. The Act thus gives to the nursing profession a status and power which it never had before. So far there has not been much connexion between the nurses' training schools and the universities in Great Britain, though this is being discussed, and in 1921 the university of Leeds decided to grant a university diploma in nursing.

*Nursing in British Dominions.*—Nursing in the Overseas Dominions is developed on lines similar to those in the United Kingdom; but there is a Colonial Nursing Association which sends trained hospital and private nurses to the Crown Colonies and small British communities in foreign countries. There is also an Indian Nursing Association (Lady Minto's) for Europeans in India.

In most civilized countries in Europe and elsewhere the Nightingale tradition has taken root, but in very many cases the idea of a controlling matron with executive powers has not been developed, and this militates against the success of the hospital as a professional training school. During the year 1920–1 the League of Red Cross Societies sent 16 nurses of different nationalities to study in a course specially arranged at King's College for Women, and this experiment may be expanded.

*British Military Nursing.*—In 1901, during the South African War, the Secretary of State for War (Mr. St. John Brodrick) appointed a committee to consider the reorganization of the Army and Indian Nursing Service and advise as to its reconstruction, he himself being chairman. From it originated Queen Alexandra's Imperial Military Nursing Service (1902). Hitherto the service had been under a lady superintendent at Netley, and the power and responsibilities of the women nurses were much restricted, since it was considered that male nurses would be paramount in time of war. Under the new constitution a Nursing Board was established with the Queen as president and the director-general of the Army Medical Service as chairman, and it advised the Secretary of State on all matters connected with the service and its organization at home and in India. The India Office, however, decided to carry on its own service, and therefore references to India are thereafter omitted. There had been a service called the Indian Nursing Service since 1881, and this remained separate from the home service. It is now named Queen Alexandra's Military Nursing Service in India, and numbers 95 members.

Queen Alexandra's Imperial Military Nursing Service was organized with a matron-in-chief at its head, and principal matron, matrons, sisters, and staff nurses subordinate to her. The duties and pay of the various grades were laid down at the time of its foundation, and regulations made as to the qualifications for entry into the service. A scheme was also formed to develop the training of orderlies for the R.A.M.C. The responsibility for carrying out the recommendations of the Nurses' Board rested with the director-general of the Army Medical Service, whose principal officer in the nursing branch of the War Office was the matron-in-chief. Reports on the nursing equipment and requirements in the various hospitals were also made by the matron-in-chief and the principal matron. Ward masters were abolished and the wards were managed by the sisters. A scheme was drawn up for the training of non-commissioned officers and men of the R.A.M.C.

In 1897 an "Army Nursing Reserve Service" was also established; it was associated with the name of Princess Christian and constituted by Royal warrant. This reserve was absorbed into the Q.A.I.M.N.S. Reserve in 1908. The principle of a standing reserve of nurses was not originally adopted by the Nursing Board as it was believed that civil hospitals and nursing associations would provide the necessary means when required, and a further reserve of this kind was established in 1910. The number of nurses in the Q.A.I.M.N. Service (Regular or First Line Nursing Service) was 290 in 1914 at the beginning of the war. Of the Reserve 200 were enrolled individually as members of the Q.A.I.M.N.S. Reserve and 600 were provided by civil hospitals and associations. Later on all became one reserve, and this reserve was expanded as required. In the first year of the war there were 2,323 fully-trained reserve nurses enrolled, and the number reached 10,304 by 1918. These were distributed throughout all the areas of war and in hospital-ships.

*Queen Alexandra's Military Families' Nursing Service.*—The Q.A.M.F.N. Service was set on foot in 1921 with the view of taking over the permanent nursing establishment of the military families' and military isolation hospitals, and it consists of matrons, sisters-in-charge and staff nurses, the rates of pay and pension being the same as those laid down for the corresponding ranks in the Q.A.I.M.N.S.

*Territorial Force Nursing Service.*—This service was established in 1907–8 in connexion with the Territorial Army that was then established, and it supplied the largest number of British nurses available at the outbreak of the World War. The purpose of the service was to maintain a staff of nurses willing, in the event of mobilization of the Territorial Army, to serve in the general hospital of the district to which they were attached. Of these hospitals 23 were instituted in various centres in England and Scotland under the scheme for medical organization. They were buildings earmarked for the purpose, though at the time used for other objects. The staff were engaged in civil pursuits, but were ready to serve whenever called upon to do so. The service had at its head an advisory council at headquarters, in order to provide for the establishment of a similar system of control in each hospital. It framed rules and made recommendations for the administration of the service, and the appointment of matrons, sisters and nurses thereto. At the head of the service is a matron-in-chief. Each hospital centre had a local committee to receive the names of nurses wishing to join the service and an organizing principal matron. The Territorial Force Association of the county was requested to assist in the appointment of this committee. The roll of sisters and nurses for each hospital was forwarded for approval to the advisory council, which was composed of professional and lay members equally. Queen Alexandra was president. The understanding as regards the Territorial Force Nursing Service was that, like the rest of the Territorial Force, it would serve only in case of invasion, or when the Territorial Force was called up. The period of training necessary for a nurse was the same as for the Q.A.I.M.N.S., *i.e.* three years. The uniform is blue-grey material edged with scarlet, and a silver T is worn as well as the service badge.

[1] Recommendations on this subject were issued after full enquiry by a committee appointed by the College of Nursing.

The scheme for a Territorial nursing service was taken up with enthusiasm both by matrons and nurses, and when war broke out in 1914, and the nurses were called up along with the Territorial Force, the staffs of the hospitals were in their places as soon as the hospitals were ready to receive them, *i.e.* within ten days. The scheme provided for each hospital having 520 beds, and 2,783 nurses were required, but it was not long before it became evident that the number would have to be increased. After nine months of the war the original staff had to be increased to 4,000, and by the end of the war 8,140 had been enrolled, of whom 2,280 served abroad. In order to supplement the trained staff "assistant nurses" holding certificates of special training (fever, etc.) were brought in, as well as members of Voluntary Aid Detachments (*see* RED CROSS). Trained nurses were dispersed throughout the hospitals where they were most needed, and two V.A.D. members replaced each trained nurse taken away. For the future the general hospitals will be much larger than before, and there will be units ready to proceed abroad requiring nursing staffs (casualty clearing stations, hospital ships, etc.). The total number required for foreign service will probably be about 4,000. The system of giving short training in military hospitals during peace-time will be further developed.

*Queen Alexandra's Royal Naval Nursing Service.*—This service is not a large one, being composed of three head sisters, seven superintending and 65 nursing sisters, all ranking as officers and taking a position immediately after the surgeons. There is also a reserve carried on through the civil hospitals which are asked to guarantee a number of nurses who will be available on the outbreak of war. The number recruited is 250. The nursing sisters are assisted in the wards by stewards and attendants of the sick-berth staff, and they give them what instruction in nursing is necessary. The latter serve on board ship. The duties of the sisters are limited to the hospitals to which they are attached, but they may be transferred to other naval hospitals at home or abroad as well as, in exceptional cases, to hospital-ships. It may be mentioned that there is not much opportunity for male nurses (excepting mental nurses and masseurs) obtaining training unless they get it through the services. It may, however, be also obtained through the National Hospital for the Paralysed and Epileptics.

*Royal Air Force Nursing Service.*—This service was established in Jan. 1921, and consists of a matron-in-chief, matrons, senior sister, sisters and staff nurses. A certificate of training for at least three years in a large civil hospital is required from candidates. Members must be over 25 and under 35 on entry and they may retire at 50: retirement is compulsory at 55. (E. S. H.)

### UNITED STATES

Increased interest in preventing disease and promoting health; the war; the influenza epidemics; the organized efforts of the nurses themselves; all contributed to the rapid development of nursing in the United States in the years 1910–21. The number of trained nurses has greatly increased; they have done good service in positions of many new kinds; standards of training have been raised and opportunities multiplied.

By 1920 about 1,600 accredited training schools were connected with hospitals, with an annual enrolment of 40–50,000; and at least 120,000 "registered" nurses were entitled by the registration laws of their states to use the designation "R.N." The usual educational requirement for admission to training in 1921 was one year of high school or its equivalent. To encourage preparation by more mature and better educated girls many universities (beginning with the university of Minnesota in 1909) established schools of nursing as part of their curriculum, and there were in 1920 ten which offered to high school graduates a five-year course combining work for the Bachelor's degree with specific training in nursing.

Trained nurses were classified in 1920 according to the kind of work done by them in three groups: (1) those who attended private patients; (2) those attached to hospitals and other institutions, for service to the patients in the institution; and (3) "public health nurses." While no exact statistics were available, it was obvious that all three groups had increased in numbers and had shared in the rising standards and growing prestige of the profession. The services of a private nurse were no longer regarded as a luxury, but were more and more recognized as a necessity in serious illness among families of moderate means. The surprising growth of provision for the sick in hospitals greatly increased the number of positions for nurses in institutions; while differentiation and specialization among hospitals, together with advances in methods of treatment, created specialized positions for nurses in connexion with X-ray work, electrotherapy, hydrotherapy, massage, anaesthetization, occupational therapy, mental illness, tuberculosis, the care of children, and other classes of patients for whom differentiated institutional provision was made. It is the third group, however, which especially demands consideration, because of the novelty of much of its work, and because of its vitality and promise of further extension.

The term "public health nursing" covers all the forms of nursing by which social action endeavours to promote health whether such work by nurses is undertaken by a private society or settlement, a hospital or clinic, or the Board of Health or Board of Education or other public authority. It may thus be supported by public funds or by private contributions, and some part of its cost is defrayed by fees from patients. It includes actual care of the sick, but is more generally an educational and preventive service, extending to members of the patient's family and designed to improve their general health. It includes the sub-divisions summarized below which deal with services of no little importance.

*District*, or *visiting* nursing, which provides service for the sick in their homes, is the oldest form, dating from 1877 in New York City. Most charitable organizations of importance now have one or more nurses attached to their staff. The visiting nursing associations usually charge a fee, according to the circumstances of the patient, based on the cost of the service (in 1921 50 cents or $1.00 a visit).

*Industrial* nursing provided for employees of manufacturing and commercial establishments was introduced in the last decade of the 19th century; it commended itself by its results and was stimulated by the workmen's compensation legislation, which indirectly puts a premium on safety and health-promoting conditions. In recent years one or more nurses have come to be regarded as an essential element in the staff of a well-organized factory or business which employs many persons; there is every reason to expect that this service will become more and more common. It is still far from standardized, being in some places limited to first-aid during working hours; in others extended to a complete visiting nursing system both for employees and for their families. In 1920 it was estimated that there were about 1,320 industrial nurses, employed by mills, factories, department stores, hotels, laundries, mining operators, insurance companies, and banks.

*Nursing service for policy-holders* was instituted as an experiment in 1909 by the Metropolitan Life Insurance Company of New York, and rapidly extended to cover all its millions of industrial policy-holders. This service usually is provided by arrangement with existing organizations, the Company paying for the cost of the visits made on its behalf. In 1918, after the system had been in operation nine years, a careful statistical study was made, which convinced the officers of the Company that the innovation had been a marked factor in the decrease of mortality among policy-holders and had more than paid for itself.

*Public school nursing*, beginning with an experiment in New York City in 1903, had become by 1920 common in the large cities, sometimes under the educational, sometimes under the health authorities.

A plan for providing visiting nurses for *rural* districts was made by the American Red Cross in 1912, and there were some 1,300 nurses engaged in this kind of work in 1920.

Other specialties in public health nursing were the care of tuberculosis patients at home, pre-natal and maternity work, child welfare and infant welfare, work with mental disorders, with venereal disease and in connexion with the bureaus of communicable and contagious disease in departments of health. The special nurse for tuberculosis, appearing with the anti-tuberculosis movement early in the present century, is coming to be the general guardian of the health of all members of the household into which she goes, and this is more or less true of other specialized visiting nurses. The development of public health nursing has been rapid, the number of nurses so engaged having increased from 130 in 1890, to 1,413 in 1909, to 6,019 in 1916 and to 11,000 in 1921, an increase out of proportion to that of population.

Nurses have three professional organizations of national scope: the American Nurses' Association, with a membership of 45,000; the National League of Nursing Education, including about 1,200 of the teachers and educational leaders in the profession; and the National Organization for Public Health Nursing, organized in 1912 to assist in the development of public health nursing, especially along the lines of education and legislation; to this lay members are eligible as well as nurses, and it has a membership of over 7,500. These organizations have had a large part in arousing public interest, in securing registration laws, in increasing and improving opportunities for training, and otherwise raising and maintaining the standards of the profession. **NYASALAND PROTECTORATE** (*see* 4.595.)—The pop. at the 1911 census was: natives 969,183, Europeans 766, Asiatics 481. In March 1920 Europeans numbered 1,015 and Asiatics 515. The natives were estimated (1919) at 561,600 males and 664,400

females, a total of 1,216,000. Blantyre, the chief town, had some 300 European residents. There were 30 persons per sq. m., the latest surveys giving the protectorate an area of 39,573 sq. miles.

During 1910–21 the country made considerable economic progress, though much hampered by inadequate means of communication with the outer world. Up to 1915 the southern terminus of the railway was on the Shire river at Port Herald, which place steamers were unable to reach in the dry season owing to insufficient water. In that year an extension of the line (61 m. long) to Chindio, on the north bank of the Zambezi, was opened. The Zambezi itself is, however, unsatisfactory as a waterway, and the direct connexion of Nyasaland with an ocean port was at length undertaken in 1920, with the building of a railway (170 m. long) from Beira to Chindio. The line progressed rapidly, and by the end of 1921 only the dredging of the Zambezi remained to be accomplished. From Beira to Port Herald the railway runs through Portuguese territory, but the Nyasaland Government guaranteed interest for 25 years on the capital (£1,200,000) of the company which built the Beira–Chindio section. In the north the Nyasaland railway ended at Blantyre, 120 m. short of Lake Nyasa with its 350 m. of waterway. In 1914 the British Parliament authorized a loan to continue the line to the lake, but owing to the World War nothing had been done up to 1921 beyond the survey of a route. On the extension of the railway to the lake depended the development of a large area suitable for cotton.

Only in a few districts is the climate suitable for Europeans, most of whom live in the Shire Highlands. But their influence, especially that of the missionaries, is felt in every part of the protectorate, and in few parts of equatorial Africa have the natives more readily responded to European influences. Education is wholly in the hands of the missionaries. Over 2,000 schools are maintained, with, in 1920, some 125,000 scholars on the roll. There are several industrial schools where agriculture, horticulture, carpentry, printing and other trades are taught. Up to 1921 an annual grant of £1,000 was the only contribution of the Government to education; no provision was made for the instruction of white children. Large numbers of the natives profess Christianity, and native churches independent of missionary control were founded under the influence of Ethiopianism.

Cotton-growing was the chief industry, though from 1918 onward it was being supplanted by tobacco. In 1916–7 the export of cotton reached 3,462,000 lb.; it fell to 866,000 lb. in 1917–8 (largely owing to shipping restrictions), rose again to 2,670,000 lb. in 1918–9, but in 1919–20 dropped to 930,000 lb. Increasing attention was given to tea, while coffee was largely discarded. (The export of coffee which was 748,000 lb. in 1909–10 had fallen to 113,000 lb. in 1918–9.) The disfavour into which cotton fell was partly due to the neglect to use selected seed and to other errors in cultivation, but also to the fact that, where soil and climate suited both crops, tobacco-growing was more profitable. After some unfortunate experiences arrangements were made in 1917 for the fumigation of the tobacco before shipment, with the result that the crop thereafter, in normal circumstances, commanded a high price in the markets of Great Britain. The export of tobacco was 4,304,000 lb. in 1916–7, fell to 2,025,000 lb. the following year, was 5,800,000 lb. in 1918–9 and 4,340,000 lb. in 1919–20. Both cotton and coffee were largely cultivated by native farmers as well as by the European planters.

The growth of trade between 1909–10 and 1913–4, the five years preceeding the World War, was marked. Exports of produce of the protectorate increased in value from £97,000 to £200,000, imports for home consumption from £111,000 to £189,000, the transit trade from £20,000 to £34,000. In the first war year (1914–5) exports fell to £182,000; they increased to £289,000 in 1916–7, fell to £144,000 the following year, but rose to the unprecedented figure of £511,000 in 1918–9, a value due in part to inflated prices. In 1919–20 the exports were valued at £430,000. Imports which in 1914–5 were valued at £181,000 were worth £648,000 in 1918–9 and £606,000 in 1919–20. Over 95% of the export trade was with the British Empire, whence came over 70% of the imports.

Revenue was £76,000 in 1909–10, had risen to £118,000 in 1914–5 and was £186,000 in 1919–20. The expenditure in the three years named was £108,000, £143,000 and £217,000. For the first time since 1914–5 expenditure exceeded revenue in 1919–20. The public debt in March 1919 was £3,190,000, nearly all (£2,998,000) advances made by the British Government to meet the expenses of the local campaign against German East Africa.

*History.*—Steady progress was made in the development of the country and the increase of well-being and civilization among the natives in the five years preceding the World War. The most powerful influence was that of the Livingstonia Mission of the United Free Church, whose destinies in Nyasaland were guided for many years by Dr. Robert Laws.

Sir Alfred Sharpe, who had served in Nyasaland since 1891 and had been governor since 1897, retired in 1910 and was succeeded (Feb. 1911) by Sir W. H. Manning, the officer who had raised the Central Africa regiment and had already served as acting-governor of the protectorate. On Sir William Manning's transference to Jamaica in 1913, Mr. (later Sir) George Smith (b. 1858) was appointed governor. The appointment of Mr. Smith, like Dr. Laws an Aberdeenian, was highly popular with the Nyasaland settlers, who are mainly Scots. Sir George proved a capable and energetic governor. When in Aug. 1914 the World War broke out Nyasaland was in an almost defenceless condition, and lay open to and was attacked by the Germans of East Africa. The governor met the crisis with promptitude and resolution, and he had the whole-hearted support of the Europeans and natives. Practically every Briton of military age in the country was enrolled in the Nyasaland Volunteer Reserve. The disablement of the only German boat on Lake Nyasa by Comm. Rhoades of the "Guendolen" on Aug. 13 1914 gave the authorities free use of its waters to send such small forces as were available to Karonga, at the north end of the lake and near the German frontier. Karonga was attacked on Sept. 9 1914, but the assailants were decisively defeated and no second invasion of Nyasaland was attempted. The arrival of an Imperial Service contingent, 1,000 strong, from South Africa in Sept. 1915 amply provided for the defence of the protectorate. Later on Nyasaland became the base for Gen. Northey's operations against the Germans. The Nyasaland battalions of the King's African Rifles served under him, while over 150,000 natives were employed as carriers.

Early in 1915, while the situation in the protectorate was still perilous, a revolt of natives occurred in the Shire Highlands. This revolt was a symptom of Ethiopianism. The leader was John Chelembwe, a full-blooded negro who had been trained as a teacher by the American Baptist Mission and sent to the United States to take a university course. On his return he had built a church and had preached the independence of Africans. His followers, about 500, were mainly persons who had recently emigrated from Portuguese Nyasaland. On Jan. 23 1915 they attacked the house of the Magomera estate. In the house were a Mr. Livingstone (a descendant of David Livingstone), his wife, and other Europeans, in all three men, three women and five children. The three men were murdered and the women and children carried off. Mr. Livingstone was killed by a blow from an axe and decapitated in the presence of his wife. Mr. Livingstone's head was taken to Chelembwe's church, and the rebel leader preached a sermon with the head placed on the pulpit. Meanwhile Mrs. MacDonald, one of the women taken captive, aided by her native servant, escaped, and barefoot and in her nightdress ran through the jungle to another planter's house. A force of 40 British volunteers and 100 natives (K.A.R. recruits) under Capt. L. E. Triscott was speedily gathered and met and defeated the rebels. Chelembwe, who took to flight, was tracked down and shot dead (Feb. 3) by the native police of Mlanje station. With Chelembwe's death the rising was at an end.

The revolt was not a reflection of the attitude of the natives. Their loyalty remained unaffected. But a weakening of the authority of chiefs was apparent, and in 1912 an ordinance was passed aiming at the concentration of scattered huts, thus bringing the people more under control of their headmen. The ordinance gradually applied, worked satisfactorily.

A considerable number of men who came from South Africa or Great Britain to serve against the Germans remained in Nyasaland as planters, and the area under cultivation largely increased. In the last half of 1920 the great fall in prices, at a time when the administration had placed heavy export duties on cotton, tea and tobacco, caused a financial crisis. In April 1921 the export duties were removed. While market fluctuations might be tided over, the future of Nyasaland remained very much dependent upon the completion of through railway communication from the ocean to Lake Nyasa.

Sharpe, "Geography and Economic Development of British Central Africa," *Geog. Journal* Jan. 1912; N. Maclean, *Africa in Transformation* (1913) and "The Times" *History of the War* (vol. x., chap. 155). (F. R. C.)

**OBREGÓN, ALVARO** (1880– ), Mexican President, was born in Nogales, Sonora, Mexico, in 1880, of Basque and Yaqui parentage. He engaged in farming, trading, and stock-raising in Sonora. He took part in the Madero revolution when Pascual Orozco threatened invasion of his state, driving the rebels out with a troop of 400 Yaquis. He joined Carranza against Huerta in 1913, winning general's rank by defeating the latter. In 1914, leading Constitutionalist forces in the West, he took Sinaloa, Culiacán and Guadalajara in July, entering the capital Aug. 15. He sided with Carranza against Villa, took Puebla in Jan. 1915, and held the capital when the generals of the Convention left for Aguascalientes Jan. 27, but moved out March 10. He won victories over Villa at Celaya April 19; at Léon, where he lost his right arm, on June 4; and at Torréon and Saltillo in Sept. As Carranza's Minister of War he negotiated with Gens. Scott and Funston for the withdrawal of Pershing's expedition in 1916. Disagreeing with the President, he resigned and returned to his estate May 1 1917. There he accumulated a fortune by control of the *garbanso* (chick-pea) crop of the W. coast. In June 1918 he became a candidate for the presidency against Gen. Pablo González and Ignacio Bonillas. In the same year he visited the United States. In March 1920 Carranza's attempts to control Sonora against Obregón's candidacy, and the arrest of the latter charged with rebellion, led him, on escaping from Mexico City, to raise a revolt which began in Sonora under the Plan of Agua Prieta on April 9. After rapid successes Obregón entered Mexico City May 8, Carranza having fled on the 5th. Adolfo de la Huerta, Obregón's lieutenant, was made provisional president, Obregón being elected President in Sept. and inaugurated Dec. 1. (*See* MEXICO.)

**O'BRIEN, PETER O'BRIEN, 1ST BARON** (1842–1914), Irish lawyer and Lord Chief Justice, was born June 29 1842, the fifth son of John O'Brien, M.P. for Limerick from 1841 to 1852. He was educated at Trinity College, Dublin, and was called to the Irish bar in 1865. He became a Q.C. in 1880, was in 1883 made Crown prosecutor and serjeant-at-law, and in 1884 became a bencher of King's Inns. In 1886 he opposed the Home Rule bill, and joined the Unionist party, becoming in 1887 solicitor-general and in 1888 attorney-general for Ireland, in which capacity he conducted many political prosecutions. He earned at this time his nickname of "Peter the Packer." In 1889 he was made Lord Chief Justice of Ireland, was created a baronet in 1891, and was raised to the peerage in 1900. He retired from the office of Lord Chief Justice in 1913, and died at Stillorgan, co. Dublin, Sept. 7 1914, his title becoming extinct.

**OCEANOGRAPHY** (*see* 19.967*).—The period following the year 1910 was not productive of notable additions to knowledge of general oceanography. Several expeditions were made just before that year and in the period between then and the World War. The most important were: the Australian Antarctic expedition of 1911–4 under Sir Douglas Mawson; the Danish Oceanographical expeditions in the Mediterranean and adjacent seas of 1908–10; a short cruise made by Sir John Murray and Dr. Johan Hjort in the Norwegian Fishery exploring vessel "Michael Sars" in 1910, the general results of which were published as *The Depths of the Ocean* (1912) by the leaders of the expedition; and a short special cruise made by the "Scotia" in 1913 (after the loss of the "Titanic") under the leadership of Dr. Matthews, which made observations upon the distribution of ice in the North Atlantic.

Generally, oceanographic work at sea was brought to a stop by the outbreak of war in 1914. A good deal of special investigation relating to naval and especially submarine warfare was carried on during 1914–8, but the results of this confidential work were not published. The very important activities of the Conseil Permanent International pour l'Exploration de la Mer were suspended during the war except in a few local seas. Fortunately the continuity of the organization was maintained, largely through the mediation of the British Government, and the council held its first post-war meeting in London in 1920. Its work is primarily that of the investigation of the fisheries of northern Europe, but its general methods are oceanographical, and its published results have formed an immense contribution to the science. Germany and Russia had, temporarily at all events, withdrawn from the coöperation, but France came in for the first time in 1920, and it was understood that the United States was likely to join in the scheme of investigation. An entirely new project was an international survey of the Mediterranean and adjacent seas, from the fishery and oceanographical standpoints, by France, Italy, Spain and Portugal, but in 1921 no definite programme had been put in operation. The International Research Council formed just after the war constituted a section for Physical Oceanography, which held its first meeting in Paris in 1921. In 1920 a very influential movement began, in England, for the despatch of a new "Challenger" expedition on a great scale, but it was suspended in 1921 for lack of funds. On the whole, oceanographical research was being taken up most actively in Europe, but much important work was also begun in America, for instance the fine hydrographical research in the Pacific by the Scripps Institute of the university of California.

*Methods of Investigation.*—Little change occurred subsequently to 1910 with regard to the methods of oceanographical investigation except a continual refinement and an increasing improvement in the apparatus used: in this direction the activities of the Central Bureau of the International Council were very noteworthy. The instruments—current-meters, sounding apparatus, water-collecting bottles, thermometers, hydrometers, etc.—were all elaborated and improved. Hydrodynamical methods received increased attention and the investigation of the movements of the ocean by means of physico-mathematical devices developed as a result of the older work of Bjerknes, continued chiefly by Helland-Hansen and Sandström. It became fairly certain, however, that theory had outrun observational work, and that the latter must again receive renewed attention.

The empirical data on which the hydrodynamical investigations are based are: (1) observed velocities and directions of oceanic currents and drifts; (2) salinity; (3) density; (4) temperature of the sea water *in situ;* (5) oceanic soundings. Given that such observations at the surface of the sea, at intermediate levels and at the bottom are sufficiently numerous and are of a high degree of precision, general conclusions as to the movements of the ocean may be deduced from established theorems in hydrodynamics. But detailed studies of the circulation of the water in any small area show deviations from the calculated results that are to be expected: thus Nansen's investigation of the Norwegian sea shows that the main directions of streaming of the water are broken up by numerous large and small vortices. So also any exhaustive survey of the temperature and salinity of the sea at a great number of points on and below the surface reveals a complexity of conditions that may defy mathematical analysis and could not easily be predicted. A very large amount of local detailed observation in the various sea-areas must be the next important work to be undertaken: this means current-observations by direct readings of metres, by the employment of drift-bottles and numerous determinations of temperature and salinity at all seasons.

*Variations in Oceanic Circulation.*—The general scheme of oceanic circulation was made out prior to 1910. The excess of heat received in equatorial regions expands the water, but at the same time excess of evaporation concentrates it, so that the density increases. The heating effect is, however, the more significant, and so the water of the ocean tends to flow N. and S. from the equator towards the poles. In intermediate latitudes there is a loss of heat and then the increased density due to equatorial concentration becomes a factor. The water sinks below the surface and continues to flow along the sea bottom back towards the equator. In the polar areas the melting of sea-ice and of ice formed by precipitation lowers the density of the sea-water and causes a difference of level which sets up streaming movements towards the equator. This surface drifting water is cold and as it enters into intermediate zones it remains colder

than the water *in situ* there and is therefore denser; it sinks below the surface and continues to flow along the bottom either back to the polar regions or towards the equator.

This main scheme is complicated in various ways: (1) by the rotation of the earth, which continually deflects currents of water or air to the right in the northern or to the left in the southern hemisphere; (2) by the conformation of the land masses (as in the case of the equatorial stream which is banked up in the Gulf of Mexico and flows out through the Straits of Florida); (3) by the varying depth of the ocean, for currents tend to flow more readily through deep than in shallow waters (as in the case of the main Atlantic drift, which flows most strongly through the deep channel between Shetland and the Faroe Is.); and (4) by the driving force of the winds acting on the surface of the sea (thus the drift of water from the equator is not N.E., as one might expect, but from E. to W., because of the impelling force of the N.E. and S.E. trade-winds).

All ocean currents vary from year to year in their strength of flow and the main interest of physical oceanography in recent years has been the tracing-out of these variations and the search for the causes. The variations themselves are detected by the method of seasonally repeated hydrographic soundings. Samples of water are collected periodically from a number of places in a large sea-area (the North or Norwegian seas, or the English Channel, for instance) at the surface, bottom and a number of intermediate levels. At the same time temperature observations are made. Stations which are placed in a straight line across a sea are then connected and "sections" are made. These show the magnitudes of the layers of different salinity and temperature beneath the surface, and when a number of sections are compared the differences from season to season and from year to year can be seen. So far only the North Atlantic has been at all well studied and evidence of seasonal and periodic variations extending over a number of years has been obtained in this area. Water drifting into the North Atlantic from the equatorial stream has a relatively high salinity (from 36‰ to 36.5‰) and a high temperature (from 15°C. to 20°C.), and when the distribution of salinity from season to season is studied it is seen that the area of dense water (salinity 36‰) extends farther to the N. in Nov. than in March. A large area of the North Atlantic is thus covered with relatively warm and dense water and this would slowly drift N. until it cooled sufficiently to sink beneath the surface. The prevailing W. and S.W. winds, however, drive it towards the N.E., where it impinges on the shallow seas and shore of northern Europe.

Taking such an easily surveyable area as the North Sea, the quantity of relatively warm and dense Atlantic water entering it from year to year can be estimated by the method of hydrographic sections. It can thus be seen that Atlantic water enters the North Sea round the N. of Shetland and (to a far less extent) through the English Channel. The flow culminates about March in each year, when a considerable part of the North Sea is covered with water of 35‰ salinity, but in Nov. the area so covered is very much less. Therefore the inflow waxes and wanes from season to season throughout the year, but it also varies in the same season in different years. There is no doubt about the latter variation, but with regard to its periodicity—that is, the number of years elapsing between one maximum and the next—much still remains to be done.

Farther to the N. of the British Isles the *superficial* drift of Atlantic water ceases, the temperature having fallen so much that the inflowing water becomes denser than that *in situ*, so that it sinks beneath the surface. It still flows on, however, as a deep current and it then becomes a factor of immense importance with regard to the fisheries in the regions into which it penetrates. The sinking-down occurs in the Kattegat when the inflowing Atlantic water enters the Baltic as an undercurrent which is both warmer and denser than that on the surface. The same thing occurs as the Atlantic stream rounds North Cape: there it breaks up into branches which are irregularly distributed and, sooner or later, sink below the surface and flow on as submarine currents. Entering the Barents Sea (that is, the area between the ice and the northern coast of Europe), these currents flow along the bottom. The inflowing Baltic undercurrent carries with it herrings and other fish from the North Sea outside, and the submarine current entering the Barents Sea also carries with it such fish as plaice. It is mainly because these fisheries are seasonal that the periodicity has been noticed, and because of the economic interests involved the study of the seasonal and longer periodicities has become very important.

As to the causes of the changes in the strength of the current from year to year much investigation has still to be made. The connexion that seemed to be first established was between variations in the quantity of water transported from the tropical to the sub-polar Atlantic and variations in the intensity of solar radiation. Helland-Hansen and Nansen traced a periodicity in the flow of Atlantic water along the W. coast of Norway: every ten to twelve years this flow appeared to reach a maximum and a graph of the variations showed a certain resemblance to the well-known graphs showing the numbers of spots on the sun from year to year. Not only so, but a similar variation was traced in the productivity of the great Lofoten (Lofoden) cod-fisheries. It was difficult to be sure as to the variations in the actual number of fish caught, but it was easy to show that there was a real variability in the yield of cod-liver oil (an important product of the fishery). Tracing, then, the quantities of oil given per 1,000 fish from year to year, they seemed to establish a connexion between the variation in "condition" of the fish, the variation in the inflow of Atlantic water, and the variation in the number of sun-spots from year to year.

The relation appeared, however, to be far more complicated than was at first supposed. Helland-Hansen and Nansen showed later that it was improbable that variations in the northerly drift of Atlantic water could be traced directly to variations in the quantity of heat received by the sea from solar radiation. Of the total quantity of energy incident on the earth about 40% is reflected back from the earth's atmosphere. Of the 60% that penetrates only about one-third actually heats up the surface of the land or sea and the rest is absorbed by the atmosphere. The heating of the latter causes great differences of pressure, which in turn set up changes of atmospheric circulation. Now it is probable that the main cause of oceanic circulation is the driving force of the winds upon the superficial layers of water; hence periodic and irregular changes in the direction and velocities of ocean currents are probably due to changes in atmospheric circulation traceable to changes in the quantities of heat absorbed from the sun by the earth's atmosphere.

Later still Hjort showed that the study of the variability in the productivity of a fishery is always a complex matter—far more so than was formerly supposed. It appeared that the quantity of oil contained in the liver of a cod (per unit of weight) increases with the age of the fish. Detailed study of the cod shoals also showed that their composition was continually changing: in some years the shoal is composed of younger or older fish than the average and with this latter variation there are changes in the quantities of oil yielded per 1,000 fish. The changes in the composition of the shoals, as regards the proportions of the various "year-classes," are to be correlated with oceanographical changes (see below). It is proper, however, to point out at once how very complicated may be the relationships between oceanographical and strictly biological phenomena, though, of course, the latter are ultimately dependent on the former.

*Long-range Periodicities in Oceanographical Changes.*—More and more the science seeks to discover periodicities and to correlate these with others. In these attempts new methods are elaborated and in their criticism contributory phenomena are discovered. An interesting example is the discussion, by Otto Pettersson, of the effects of long-range fluctuations in the tide-generating force: this memoir was published about 1914, but has only recently become available to English readers.

The tide-generating force is due to the attraction of the waters of the ocean by sun and moon. There are two gravitational fields which sometimes reinforce and at other times diminish each other and the effect is always a resultant one. There are therefore maxima and minima in the value of the tide-generating force, depending on the relative positions of the sun, earth and moon. The orbits of earth and moon are elliptical, so that the earth is sometimes nearer, sometimes farther away from the sun, and the same is the case with the moon in relation to the earth. The orbital planes of earth and moon are inclined to each other at an angle of 5° 8′ and at two points only in its orbit can the moon be situated in the plane of the ecliptic: the line joining these two points is called the "line of nodes." A line joining the moon in perigee and in apogee is called the "line of apsides." Now such a constellation as the following must sometimes exist: the earth is in perihelion; the line of nodes coincides with the line of apsides and both lie in the line joining earth and sun. The line of nodes rotates in a period of 18·612 years and the line of apsides in a period of 8·84 years. Such a constellation can be shown to occur at intervals of about 1,800 years and about those times the tide-generating force will be at an absolute maximum. Working out the calculations, Pettersson finds that the favourable constellation occurred and will occur in 3500 B.C., 1900 B.C., 250 B.C., 1433 A.D., 3300 A.D., and so on. In addition to these there are subsidiary maxima at intervals of 4½, 9 and 84–93 years.

Given, then, that the variations in tide-generating force are big enough, the periods when the maxima occur will be critical with regard to oceanographical and meteorological phenomena. About the time of the maxima there must be a longer tidal range (that is, a greater rise and fall than the average); the difference between neap tides and spring tides will also be increased, and as results of these conditions there must be great tidal floods breaking over low-lying coasts and producing extensive denudation. Pettersson further deduces sharp extremes of climate and great temperature contrasts. Far inland he supposes there will be devastating droughts. An effect of the greater tide-generating force will also be instability of the liquid magmas underlying volcanic areas, leading to violent eruptions and earthquakes. There will be great outbursts of polar ice, but this will melt at higher latitudes than in the periods when the tide-generating force is minimal.

It is shown to be probable that such effects actually occurred about the time of the last maximum (A.D. 1433). There is evidence that, towards the close of the mediaeval period, great storms and tidal inundations occurred on the shores of the North Sea and Baltic, and in the course of these floods, culminating in 1297, the Zuider Zee was formed from a lake that existed in its neighbourhood, by the breaking down of dykes. (Similar effects can be seen on a small scale, even in our own times, as the result of exceptionally big tides.) Severe winters were experienced and the Baltic was frequently frozen over so that there was solid ice communication between Sweden and Denmark across the Belts and Sound: this happened in the 13th, 14th and 15th centuries but not in the 16th. There have been great differences in the seas round Iceland and Greenland with regard to the presence of ice: from the 9th to the 12th centuries there is no evidence (in contemporary accounts) of the presence of much ice in the sea off Greenland, nor was much ice carried by the Labrador current, but from the 13th century onwards we do have evidence that there was very troublesome ice off Greenland. Hence from the 10th to the 12th centuries there was great intercourse with Iceland and Greenland on the part of the English, Swedish and Danish, but at the end of the 13th century some change occurred, resulting in the southerly emigration of the Eskimos and the extinction of European civilization in Greenland. At the present time the S. and E. coasts are icebound, and the W. coast, though icebergs are present in the adjoining sea, is clear. Many economic changes probably occurred in consequence of the variations in tide-generating force, as, for instance, the decline in the mediaeval Baltic herring fisheries controlled by the Hanseatic League.

*Hydrobiology.*—The study of marine life has in recent years become more general, and has become associated with very precise investigations into the chemical composition of sea-water, changes in chemical equilibrium, the effect of variations in salinity and temperature, the processes set up by marine bacteria, and so on. The investigation of the microscopic pelagic life of the sea has also developed to a great extent. Several decades ago all marine organisms became grouped together in three great categories: (1) the *Benthos*, or bottom-living, rooted or sedentary forms; (2) the *Nekton*, or actively swimming animals; and (3) the *Plankton*, or drifting (usually) microscopic organisms, which have little power of locomotion (*see* 21.720). The plankton is divided into (*a*) the *Zoö-plankton* (such as the minute crustacea and the eggs and larvæ of fishes and many other marine animals); and (*b*) the *Phyto-plankton*, that is, the minute algae, diatoms, peridinians, some flagellate protozoa, spores of algæ, etc. The investigation of the plankton from a new point of view, begun by Hansen in 1889, was continued by Lohmann at Kiel, by Cleve in Sweden, by Gran and Ostenfeldt in Norway and Denmark, and by Herdman, Allen and others in England. Hansen's early results were much criticized and the original methods very greatly modified and improved. It became clear that only very rough estimates of the numbers of planktonic organisms in a volume of sea-water as large as (say) 10 cubic metres could be made, but that these estimates could nevertheless be trusted to show very marked regional and seasonal differences.

*Distribution of the Plankton.*—In general the plankton—and especially the phyto-plankton of the polar and temperate seas—is much more abundant than is that of the sub-tropical and tropical zones. All forms of plankton are more abundant in the shallow coastal waters of relatively low salinity. Finally, the plankton (and again the vegetable forms in particular) are practically restricted to the upper hundred fathoms or so of the sea. Deeper than this, microscopic life is scanty; there is practically no reproduction and growth. These facts of distribution are due to certain conditions that govern the production of organic substance in the oceans.

*Holozoic and Holyphytic Organisms.*—These terms relate to the modes of nutrition. Typical animals are holozoic, that is, they obtain their food by eating the tissues of other animals and plants: they take their food substances in the organized forms of proteids, fats and carbohydrates. Typical plants are holophytic, that is, they obtain their food substances from purely mineral sources. Water and carbonic acid are synthesized, under the action of sunlight, to form sugar, starch or some other carbohydrate and this is then combined with simple nitrogenous salts to form proteid. Fats doubtless originate by the "cleavage" of the synthetically formed proteids, or from carbohydrates. Now dead animal substance and the excreta of animals decompose in the long run into carbonic acid, water and mineral salts, and so there is a continual destruction of animal substance both on the land and in the sea. Animals cannot make use of these decomposition products, but the plants can. Therefore all life in the sea (as on land) depends on the power which the holophytic organisms possess of synthesizing mineral substances into organised tissues. This is mainly effected, in the sea, by the phyto-plankton.

*Ultimate Food Substances in the Sea.*—These are the materials which are utilized by the vegetable plankton in the synthesis of living material: they are water, carbonic acid, nitrates and nitrites of calcium, magnesium and other earthy and alkaline metals, phosphates, silica, traces of salts containing iron, sulphur, potassium and a few other elements. Except the water, all are present in the sea in exceedingly small proportion. The source of the carbon of organic tissues is carbonic acid; that of the nitrogen in the proteids is the nitrates, nitrites and salts of ammonia dissolved in sea-water; the material of the shells or other skeletons is the silica, phosphate and calcium of the salts of sea-water (and, in rare cases, the salts of strontium). All these substances exist as only a fraction of one part or, at most, a few parts, per million of water. Carbonic acid is the most abundant and it may be contained in sea-water in the proportion of about 50 milligrammes per litre (that is, 50 per million). All of this is not available, for carbonic acid is present as such in solution, as bicarbonate (of magnesium mainly) and as normal carbonate. Only the "free" carbonic acid and that of the bicarbonate can be utilised in the process of photosynthesis by the diatoms and algæ.

Mineral nitrogenous compounds (nitrates, nitrites and ammonia) are much more rare. The distribution is very interesting and it has been shown that the water of the Antarctic Ocean contains about 0·5 part per million of nitrogen in the above forms. The North Atlantic contains, on the average, about 0·15 part per million and the equatorial seas little more than about 0·1 part per million. The proportion varies with the temperature. There is more inorganic nitrogen in the sea near the land than in mid-ocean and there is more at the sea bottom than near the surface; finally, there is more in the later winter than at any other season. Silica (which is required for the skeletons of diatoms, radiolaria, peridinians, etc.) is present in about the same concentration, but it is now suspected that a source of this substance may be clay washed down from the land and present in the sea in the colloidal form. Phosphates, necessary for the formation of skeletons and also for the nucleo-proteid of cells, are about as scarce as nitrogen. In the case of all these substances the quantities involved are so very small, and the difficulties of estimation are therefore so great, that the information we possess is by no means satisfactory. Clearly, however, the vast quantity of living substance in the ocean is built up from materials that are present in the sea-water as an exceedingly dilute solution, and the solution is dilute just because organisms are incessantly utilizing it. It follows, too, that when there is a number of substances, all essential for the elaboration of living material, and when one of these is present in minimal proportion, that one substance rules the production, just as the effective strength of a chain depends on the weakest link. This is Liebig's "law of the minimum."

*Seasonal Periodicities of Life in the Sea.*—In the temperate seas the two great features are: (1) the outburst of vegetable life in the spring; and (2) the vernal or summer phase of reproduction among animals. The low temperature of the winter allows (indirectly) an accumulation of the essential nitrogenous mineral salts, but as the minimal temperature is passed (in Feb. or March) and the days begin to lengthen the phyto-planktonic organisms begin to reproduce. Carbonic acid is taken from the water and synthesized (by the mediation of light energy) into carbohydrate. The carbonic acid is taken from solution and then bicarbonate (usually that of magnesium) dissociates into carbonic acid and normal carbonate, and the process of photosynthesis ceases when there is no more bicarbonate in solution. The result of this is that the *alkalinity* of the sea-water increases and the hydrogen-ion concentration decreases. Perfectly pure distilled sea-water dissociates, to an infinitesimal degree, into hydrogen (H) and hydroxyl (HO) ions, so that one litre of such water contains

$1 \times 10^{-7}$, or $\frac{1}{10{,}000{,}000}$ part of a gram-molecule of either hydrogen or hydroxyl (a gramme-molecule of hydrogen is 2 grammes, or of hydroxyl 17 grammes). Pure water, then, has a hydrogen-ion concentration of $10^{-7}$ but sea-water gives (because of the mixture of the salts in solution) the concentration $10^{-8\cdot2}$ and when photosynthesis by the larger algæ, or diatoms, is very active this figure falls to about $10^{-9\cdot1}$. That is, the concentration of H-ions decreases and that of the HO-ions increases; the water becomes more alkaline because the carbonic acid of the bicarbonate has been abstracted by the phyto-plankton to the extent that normal carbonate is left. When that condition is attained photosynthesis slows down and ceases.

The spring outburst of plant life in the sea culminates about April, just about the time when the temperature of the water begins to rise rapidly. The increasing temperature raises the rate of animal metabolism, while the higher alkalinity is a stimulus to cell-division. Therefore the animal organisms, as a rule, reproduce in the spring or early summer just after the vernal phyto-plankton maximum. From then onwards the plant organisms diminish because they are eaten by the animal larvæ.

The numerical values are, it is to be noted, exceedingly small. Experiments made by Moore and Whitley at Port Erin in the Isle of Man show that the hydrogen-ion concentration falls from about $10^{-8\cdot1}$ in Dec. to about $10^{-8\cdot4}$ in April. This corresponds to an increased alkalinity represented by about 2 c.c. of N/100 standard alkali, and that difference means that the carbon of about 8·8 milligrammes of carbonic acid has been built up (by photosynthesis) into carbohydrate during the period during which the change in alkalin-

than the water *in situ* there and is therefore denser; it sinks below the surface and continues to flow along the bottom either back to the polar regions or towards the equator.

This main scheme is complicated in various ways: (1) by the rotation of the earth, which continually deflects currents of water or air to the right in the northern or to the left in the southern hemisphere; (2) by the conformation of the land masses (as in the case of the equatorial stream which is banked up in the Gulf of Mexico and flows out through the Straits of Florida); (3) by the varying depth of the ocean, for currents tend to flow more readily through deep than in shallow waters (as in the case of the main Atlantic drift, which flows most strongly through the deep channel between Shetland and the Faroe Is.); and (4) by the driving force of the winds acting on the surface of the sea (thus the drift of water from the equator is not N.E., as one might expect, but from E. to W., because of the impelling force of the N.E. and S.E. trade-winds).

All ocean currents vary from year to year in their strength of flow and the main interest of physical oceanography in recent years has been the tracing-out of these variations and the search for the causes. The variations themselves are detected by the method of seasonally repeated hydrographic soundings. Samples of water are collected periodically from a number of places in a large sea-area (the North or Norwegian seas, or the English Channel, for instance) at the surface, bottom and a number of intermediate levels. At the same time temperature observations are made. Stations which are placed in a straight line across a sea are then connected and "sections" are made. These show the magnitudes of the layers of different salinity and temperature beneath the surface, and when a number of sections are compared the differences from season to season and from year to year can be seen. So far only the North Atlantic has been at all well studied and evidence of seasonal and periodic variations extending over a number of years has been obtained in this area. Water drifting into the North Atlantic from the equatorial stream has a relatively high salinity (from 36‰ to 36.5‰) and a high temperature (from 15°C. to 20°C.), and when the distribution of salinity from season to season is studied it is seen that the area of dense water (salinity 36‰) extends farther to the N. in Nov. than in March. A large area of the North Atlantic is thus covered with relatively warm and dense water and this would slowly drift N. until it cooled sufficiently to sink beneath the surface. The prevailing W. and S.W. winds, however, drive it towards the N.E., where it impinges on the shallow seas and shore of northern Europe.

Taking such an easily surveyable area as the North Sea, the quantity of relatively warm and dense Atlantic water entering it from year to year can be estimated by the method of hydrographic sections. It can thus be seen that Atlantic water enters the North Sea round the N. of Shetland and (to a far less extent) through the English Channel. The flow culminates about March in each year, when a considerable part of the North Sea is covered with water of 35‰ salinity, but in Nov. the area so covered is very much less. Therefore the inflow waxes and wanes from season to season throughout the year, but it also varies in the same season in different years. There is no doubt about the latter variation, but with regard to its periodicity—that is, the number of years elapsing between one maximum and the next—much still remains to be done.

Farther to the N. of the British Isles the *superficial* drift of Atlantic water ceases, the temperature having fallen so much that the inflowing water becomes denser than that *in situ*, so that it sinks beneath the surface. It still flows on, however, as a deep current and it then becomes a factor of immense importance with regard to the fisheries in the regions into which it penetrates. The sinking-down occurs in the Kattegat when the inflowing Atlantic water enters the Baltic as an undercurrent which is both warmer and denser than that on the surface. The same thing occurs as the Atlantic stream rounds North Cape: there it breaks up into branches which are irregularly distributed and, sooner or later, sink below the surface and flow on as submarine currents. Entering the Barents Sea (that is, the area between the ice and the northern coast of Europe), these currents flow along the bottom. The inflowing Baltic undercurrent carries with it herrings and other fish from the North Sea outside, and the submarine current entering the Barents Sea also carries with it such fish as plaice. It is mainly because these fisheries are seasonal that the periodicity has been noticed, and because of the economic interests involved the study of the seasonal and longer periodicities has become very important.

As to the causes of the changes in the strength of the current from year to year much investigation has still to be made. The connexion that seemed to be first established was between variations in the quantity of water transported from the tropical to the sub-polar Atlantic and variations in the intensity of solar radiation. Helland-Hansen and Nansen traced a periodicity in the flow of Atlantic water along the W. coast of Norway: every ten to twelve years this flow appeared to reach a maximum and a graph of the variations showed a certain resemblance to the well-known graphs showing the numbers of spots on the sun from year to year. Not only so, but a similar variation was traced in the productivity of the great Lofoten (Lofoden) cod-fisheries. It was difficult to be sure as to the variations in the actual number of fish caught, but it was easy to show that there was a real variability in the yield of cod-liver oil (an important product of the fishery). Tracing, then, the quantities of oil given per 1,000 fish from year to year, they seemed to establish a connexion between the variation in "condition" of the fish, the variation in the inflow of Atlantic water, and the variation in the number of sun-spots from year to year.

The relation appeared, however, to be far more complicated than was at first supposed. Helland-Hansen and Nansen showed later that it was improbable that variations in the northerly drift of Atlantic water could be traced directly to variations in the quantity of heat received by the sea from solar radiation. Of the total quantity of energy incident on the earth about 40% is reflected back from the earth's atmosphere. Of the 60% that penetrates only about one-third actually heats up the surface of the land or sea and the rest is absorbed by the atmosphere. The heating of the latter causes great differences of pressure, which in turn set up changes of atmospheric circulation. Now it is probable that the main cause of oceanic circulation is the driving force of the winds upon the superficial layers of water; hence periodic and irregular changes in the direction and velocities of ocean currents are probably due to changes in atmospheric circulation traceable to changes in the quantities of heat absorbed from the sun by the earth's atmosphere.

Later still Hjort showed that the study of the variability in the productivity of a fishery is always a complex matter—far more so than was formerly supposed. It appeared that the quantity of oil contained in the liver of a cod (per unit of weight) increases with the age of the fish. Detailed study of the cod shoals also showed that their composition was continually changing: in some years the shoal is composed of younger or older fish than the average and with this latter variation there are changes in the quantities of oil yielded per 1,000 fish. The changes in the composition of the shoals, as regards the proportions of the various "year-classes," are to be correlated with oceanographical changes (see below). It is proper, however, to point out at once how very complicated may be the relationships between oceanographical and strictly biological phenomena, though, of course, the latter are ultimately dependent on the former.

*Long-range Periodicities in Oceanographical Changes.*—More and more the science seeks to discover periodicities and to correlate these with others. In these attempts new methods are elaborated and in their criticism contributory phenomena are discovered. An interesting example is the discussion, by Otto Pettersson, of the effects of long-range fluctuations in the tide-generating force: this memoir was published about 1914, but has only recently become available to English readers.

The tide-generating force is due to the attraction of the waters of the ocean by sun and moon. There are two gravitational fields which sometimes reinforce and at other times diminish each other and the effect is always a resultant one. There are therefore maxima and minima in the value of the tide-generating force, depending on the relative positions of the sun, earth and moon. The orbits of earth and moon are elliptical, so that the earth is sometimes nearer, sometimes farther away from the sun, and the same is the case with the moon in relation to the earth. The orbital planes of earth and moon are inclined to each other at an angle of 5° 8′ and at two points only in its orbit can the moon be situated in the plane of the ecliptic: the line joining these two points is called the "line of nodes." A line joining the moon in perigee and in apogee is called the "line of apsides." Now such a constellation as the following must sometimes exist: the earth is in perihelion; the line of nodes coincides with the line of apsides and both lie in the line joining earth and sun. The line of nodes rotates in a period of 18·612 years and the line of apsides in a period of 8·84 years. Such a constellation can be shown to occur at intervals of about 1,800 years and about those times the tide-generating force will be at an absolute maximum. Working out the calculations, Pettersson finds that the favourable constellation occurred and will occur in 3500 B.C., 1900 B.C., 250 B.C., 1433 A.D., 3300 A.D., and so on. In addition to these there are subsidiary maxima at intervals of 4½, 9 and 84–93 years.

Given, then, that the variations in tide-generating force are big enough, the periods when the maxima occur will be critical with regard to oceanographical and meteorological phenomena. About the time of the maxima there must be a longer tidal range (that is, a greater rise and fall than the average); the difference between neap tides and spring tides will also be increased, and as results of these conditions there must be great tidal floods breaking over low-lying coasts and producing extensive denudation. Pettersson further deduces sharp extremes of climate and great temperature contrasts. Far inland he supposes there will be devastating droughts. An effect of the greater tide-generating force will also be instability of the liquid magmas underlying volcanic areas, leading to violent eruptions and earthquakes. There will be great outbursts of polar ice, but this will melt at higher latitudes than in the periods when the tide-generating force is minimal.

It is shown to be probable that such effects actually occurred about the time of the last maximum (A.D. 1433). There is evidence that, towards the close of the mediaeval period, great storms and tidal inundations occurred on the shores of the North Sea and Baltic, and in the course of these floods, culminating in 1297, the Zuider Zee was formed from a lake that existed in its neighbourhood, by the breaking down of dykes. (Similar effects can be seen on a small scale, even in our own times, as the result of exceptionally big tides.) Severe winters were experienced and the Baltic was frequently frozen over so that there was solid ice communication between Sweden and Denmark across the Belts and Sound: this happened in the 13th, 14th and 15th centuries but not in the 16th. There have been great differences in the seas round Iceland and Greenland with regard to the presence of ice: from the 9th to the 12th centuries there is no evidence (in contemporary accounts) of the presence of much ice in the sea off Greenland, nor was much ice carried by the Labrador current, but from the 13th century onwards we do have evidence that there was very troublesome ice off Greenland. Hence from the 10th to the 12th centuries there was great intercourse with Iceland and Greenland on the part of the English, Swedish and Danish, but at the end of the 13th century some change occurred, resulting in the southerly emigration of the Eskimos and the extinction of European civilization in Greenland. At the present time the S. and E. coasts are icebound, and the W. coast, though icebergs are present in the adjoining sea, is clear. Many economic changes probably occurred in consequence of the variations in tide-generating force, as, for instance, the decline in the mediaeval Baltic herring fisheries controlled by the Hanseatic League.

*Hydrobiology.*—The study of marine life has in recent years become more general, and has become associated with very precise investigations into the chemical composition of sea-water, changes in chemical equilibrium, the effect of variations in salinity and temperature, the processes set up by marine bacteria, and so on. The investigation of the microscopic pelagic life of the sea has also developed to a great extent. Several decades ago all marine organisms became grouped together in three great categories: (1) the *Benthos*, or bottom-living, rooted or sedentary forms; (2) the *Nekton*, or actively swimming animals; and (3) the *Plankton*, or drifting (usually) microscopic organisms, which have little power of locomotion (*see* 21.720). The plankton is divided into (*a*) the *Zoö-plankton* (such as the minute crustacea and the eggs and larvæ of fishes and many other marine animals); and (*b*) the *Phyto-plankton*, that is, the minute algae, diatoms, peridinians, some flagellate protozoa, spores of algæ, etc. The investigation of the plankton from a new point of view, begun by Hansen in 1889, was continued by Lohmann at Kiel, by Cleve in Sweden, by Gran and Ostenfeldt in Norway and Denmark, and by Herdman, Allen and others in England. Hansen's early results were much criticized and the original methods very greatly modified and improved. It became clear that only very rough estimates of the numbers of planktonic organisms in a volume of sea-water as large as (say) 10 cubic metres could be made, but that these estimates could nevertheless be trusted to show very marked regional and seasonal differences.

*Distribution of the Plankton.*—In general the plankton—and especially the phyto-plankton of the polar and temperate seas—is much more abundant than is that of the sub-tropical and tropical zones. All forms of plankton are more abundant in the shallow coastal waters of relatively low salinity. Finally, the plankton (and again the vegetable forms in particular) are practically restricted to the upper hundred fathoms or so of the sea. Deeper than this, microscopic life is scanty; there is practically no reproduction and growth. These facts of distribution are due to certain conditions that govern the production of organic substance in the oceans.

*Holozoic and Holyphytic Organisms.*—These terms relate to the modes of nutrition. Typical animals are holozoic, that is, they obtain their food by eating the tissues of other animals and plants: they take their food substances in the organized forms of proteids, fats and carbohydrates. Typical plants are holophytic, that is, they obtain their food substances from purely mineral sources. Water and carbonic acid are synthesized, under the action of sunlight, to form sugar, starch or some other carbohydrate and this is then combined with simple nitrogenous salts to form proteid. Fats doubtless originate by the "cleavage" of the synthetically formed proteids, or from carbohydrates. Now dead animal substance and the excreta of animals decompose in the long run into carbonic acid, water and mineral salts, and so there is a continual destruction of animal substance both on the land and in the sea. Animals cannot make use of these decomposition products, but the plants can. Therefore all life in the sea (as on land) depends on the power which the holophytic organisms possess of synthesizing mineral substances into organised tissues. This is mainly effected, in the sea, by the phyto-plankton.

*Ultimate Food Substances in the Sea.*—These are the materials which are utilized by the vegetable plankton in the synthesis of living material: they are water, carbonic acid, nitrates and nitrites of calcium, magnesium and other earthy and alkaline metals, phosphates, silica, traces of salts containing iron, sulphur, potassium and a few other elements. Except the water, all are present in the sea in exceedingly small proportion. The source of the carbon of organic tissues is carbonic acid; that of the nitrogen in the proteids is the nitrates, nitrites and salts of ammonia dissolved in sea-water; the material of the shells or other skeletons is the silica, phosphate and calcium of the salts of sea-water (and, in rare cases, the salts of strontium). All these substances exist as only a fraction of one part or, at most, a few parts, per million of water. Carbonic acid is the most abundant and it may be contained in sea-water in the proportion of about 50 milligrammes per litre (that is, 50 per million). All of this is not available, for carbonic acid is present as such in solution, as bicarbonate (of magnesium mainly) and as normal carbonate. Only the "free" carbonic acid and that of the bicarbonate can be utilised in the process of photosynthesis by the diatoms and algæ.

Mineral nitrogenous compounds (nitrates, nitrites and ammonia) are much more rare. The distribution is very interesting and it has been shown that the water of the Antarctic Ocean contains about 0·5 part per million of nitrogen in the above forms. The North Atlantic contains, on the average, about 0·15 part per million and the equatorial seas little more than about 0·1 part per million. The proportion varies with the temperature. There is more inorganic nitrogen in the sea near the land than in mid-ocean and there is more at the sea bottom than near the surface; finally, there is more in the later winter than at any other season. Silica (which is required for the skeletons of diatoms, radiolaria, peridinians, etc.) is present in about the same concentration, but it is now suspected that a source of this substance may be clay washed down from the land and present in the sea in the colloidal form. Phosphates, necessary for the formation of skeletons and also for the nucleo-proteid of cells, are about as scarce as nitrogen. In the case of all these substances the quantities involved are so very small, and the difficulties of estimation are therefore so great, that the information we possess is by no means satisfactory. Clearly, however, the vast quantity of living substance in the ocean is built up from materials that are present in the sea-water as an exceedingly dilute solution, and the solution is dilute just because organisms are incessantly utilizing it. It follows, too, that when there is a number of substances, all essential for the elaboration of living material, and when one of these is present in minimal proportion, that one substance rules the production, just as the effective strength of a chain depends on the weakest link. This is Liebig's "law of the minimum."

*Seasonal Periodicities of Life in the Sea.*—In the temperate seas the two great features are: (1) the outburst of vegetable life in the spring; and (2) the vernal or summer phase of reproduction among animals. The low temperature of the winter allows (indirectly) an accumulation of the essential nitrogenous mineral salts, but as the minimal temperature is passed (in Feb. or March) and the days begin to lengthen the phyto-planktonic organisms begin to reproduce. Carbonic acid is taken from the water and synthesized (by the mediation of light energy) into carbohydrate. The carbonic acid is taken from solution and then bicarbonate (usually that of magnesium) dissociates into carbonic acid and normal carbonate, and the process of photosynthesis ceases when there is no more bicarbonate in solution. The result of this is that the *alkalinity* of the sea-water increases and the hydrogen-ion concentration decreases. Perfectly pure distilled sea-water dissociates, to an infinitesimal degree, into hydrogen (H) and hydroxyl (HO) ions, so that one litre of such water contains

$1 \times 10^{-7}$, or $\frac{1}{10{,}000{,}000}$ part of a gram-molecule of either hydrogen or hydroxyl (a gramme-molecule of hydrogen is 2 grammes, or of hydroxyl 17 grammes). Pure water, then, has a hydrogen-ion concentration of $10^{-7}$ but sea-water gives (because of the mixture of the salts in solution) the concentration $10^{-8\cdot2}$ and when photosynthesis by the larger algæ, or diatoms, is very active this figure falls to about $10^{-9\cdot1}$. That is, the concentration of H-ions decreases and that of the HO-ions increases; the water becomes more alkaline because the carbonic acid of the bicarbonate has been abstracted by the phyto-plankton to the extent that normal carbonate is left. When that condition is attained photosynthesis slows down and ceases.

The spring outburst of plant life in the sea culminates about April, just about the time when the temperature of the water begins to rise rapidly. The increasing temperature raises the rate of animal metabolism, while the higher alkalinity is a stimulus to cell-division. Therefore the animal organisms, as a rule, reproduce in the spring or early summer just after the vernal phyto-plankton maximum. From then onwards the plant organisms diminish because they are eaten by the animal larvæ.

The numerical values are, it is to be noted, exceedingly small. Experiments made by Moore and Whitley at Port Erin in the Isle of Man show that the hydrogen-ion concentration falls from about $10^{-8\cdot1}$ in Dec. to about $10^{-8\cdot4}$ in April. This corresponds to an increased alkalinity represented by about 2 c.c. of N/100 standard alkali, and that difference means that the carbon of about 8·8 milligrammes of carbonic acid has been built up (by photosynthesis) into carbohydrate during the period during which the change in alkalin-

AGRICULTURAL PRODUCTION (1919)
(U.S. Census Reports)

| Crop | Quantity | Increase Per cent over 1909 | Value | Increase Per cent over 1909 |
|---|---|---|---|---|
| All crops | | | $607,037,562 | 174·6 |
| Cereals, total (bus.) | 259,547,851 | 4·8 | 391,834,355 | 184·1 |
| Corn (bus.) | 149,844,626 | −4·9 | 217,274,709 | 163·9 |
| Oats (bus.) | 46,818,330 | −18·7 | 39,795,590 | 71·4 |
| Wheat (bus.) | 58,124,351 | 89·6 | 127,873,574 | 311·0 |
| Beans, peas, peanuts, flaxseed, sugar-beet seed | | | 281,767 | 558·4 |
| Seeds: Clover, alfalfa, timothy, etc. (bus.) | 309,968 | 7·4 | 5,978,760 | 321·2 |
| Hay and forage (tons) | 7,661,890 | | 130,187,929 | |
| Vegetables | | | 43,365,158 | 107·7 |
| Miscellaneous, total | | | 20,216,824 | 90·4 |
| Tobacco (lb.) | 64,420,472 | −27·3 | 13,528,302 | 50·3 |
| Fruits and nuts | | | 15,172,769 | 93·1 |

The total for cereals includes barley, rye, buckwheat, and mixed crops besides corn, oats and wheat. "Miscellaneous" includes tobacco, sorghum, sugar-beets, maple sugar, broom corn, hemp, ginseng and minor crops. The total acreage harvested in 1919 was 11,780,554, an increase of 3·1% over 1909.

*Mineral Products.*—In 1918 Ohio ranked fifth among the states in the value of the products of mining industries in general, fourth in the amount of bituminous coal produced. From 1900 to 1918 there was an increase in the annual output of bituminous coal from 16,900,000 short tons to 40,900,000, an increase of 142% which was about the rate of increase in other coal-mining states. Ohio produced 7·6% of the bituminous coal of the United States in 1917. Of this 85·7% was mined by machinery, mostly electrically driven. The coal of Ohio is produced mainly in the south-eastern part of the state, in Belmont, Athens, Jefferson, Guernsey, Perry and Hocking counties. The fire-clay mines of Tuscarawas, Jefferson, Columbiana, Stark and Carroll counties supply the raw material for a rapidly rising industry. In coke Ohio ranked third (1917) with a production of 3,694,302 net tons; in the value of its natural gas output (1918) it was fourth, $24,234,741. As a producer of crude petroleum Ohio has fallen far behind in recent years; the total for 1918 was 7,285,005 bar. with a value of $23,465,197.

*Manufactures.*—According to the preliminary report of the census bureau for the year 1919, manufactured products were valued at $5,100,298,728; the average number of wage-earners was 730,733, and the value added by manufacture, $2,189,460,420. The pig-iron tonnage, 8,700 tons in 1918, was nearly as great as that of Great Britain at the same time. The most notable advance in the decade was in the production of motor-cars, in which Ohio ranked next to Michigan, and in the manufacture of motor-car tires. The following table shows the relative importance in 1914 of leading manufacturing industries the value of whose products exceeded $25,000,000:—

| Industry | No. of Wage-Earners | Value of Products | Increase Per cent 1909–14 |
|---|---|---|---|
| All industries | 510,435 | $1,782,808,279 | 24·0 |
| Iron and steel | 46,397 | 205,023,391 | 3·7 |
| Foundries, machine shops | 73,103 | 178,855,069 | 22·6 |
| Rubber goods | 21,705 | 109,658,605 | 103·4 |
| Automobiles, etc. | 18,752 | 85,710,585 | 120·7 |
| Blast furnaces | 5,786 | 72,969,368 | 12·8 |
| Meat-packing | 3,619 | 66,674,379 | 31·2 |
| Printing and publishing | 18,070 | 55,608,924 | 33·5 |
| Flour-milling, etc. | 2,363 | 45,171,200 | 6·1 |
| Brick and tile products | 27,334 | 38,667,374 | 26·6 |
| Electrical apparatus | 12,695 | 36,120,978 | 92·4 |
| Boots and shoes | 14,674 | 33,641,705 | 6·6 |
| Railway cars, etc.* | 21,639 | 33,286,205 | 16·0 |
| Bakery products | 7,665 | 30,560,881 | 32·8 |
| Liquors, malt | 5,340 | 31,990,274 | 26·3 |
| Timber products | 11,921 | 31,852,694 | 7·9 |
| Tobacco manufactures | 13,282 | 28,467,079 | 1·5 |
| Men's clothing | 10,758 | 27,621,829 | 11·1 |
| Food preparations | 1,523 | 27,346,187 | 152·3 |

* Includes only operations of steam railways in building their own equipment.

The true value of all property in Ohio was estimated in 1912 at $8,908,432,943, but with all its varied industries the *per capita* wealth ($1,868) was below that of other manufacturing states such as New York, Pennsylvania, Illinois, New Jersey, Connecticut and Michigan, and that of agricultural states such as Minnesota, Iowa, Nebraska, Kansas, Oklahoma and California.

*History.*—The chief political advance in the decade 1910–20 was the progress in adapting the constitution and the system of administration to the new needs of the state.

The constitution was made in 1851 for a frontier agricultural community, and no important changes had occurred in 60 years. A revision of the constitution in 1874 was defeated at the polls, largely because of the clauses on taxation. It was, however, the beginning of a struggle for the readjustment of the system of taxation to meet more complex social conditions. A proposal to hold a convention in 1891 was rejected by the voters. As the end of another 20 years approached, the Ohio Board of Commerce, which was conducting the campaign for tax reform, started a movement for a general constitutional convention. Several groups, like the Ohio Direct Legislation League, which advocated the initiative and the referendum, and the liquor interests that saw an opportunity to secure a licensing system, supported the movement, which was endorsed by both political parties. At the election of 1910 a convention was almost unanimously approved. Delegates were chosen in Nov. 1911, and the convention sat Jan.–June 1912. The delegates, of whom the majority were Democrats, represented the progressive elements of both major parties. Forty-two amendments were submitted to the voters on Sept. 3, 1912, of which 34 were ratified. Among the proposals defeated were those for the abolition of capital punishment, woman suffrage, the use of voting machines, and $50,000,000 bond issue for a state system of roads. In the convention itself the tax reformers lost their main battle for a classification of property for purposes of taxation. Indeed the convention and the voters approved a clause which was intended to make it more difficult for supporters of tax reform to succeed. The tax reformers did secure for the General Assembly the power to impose, if it would, inheritance, income and franchise taxes as well as taxes upon the production of coal, oil, gas and other minerals. A tax commission of three created in 1910 did succeed in bringing out for taxation the property of corporations at something near a true valuation, and in obtaining the adoption of the 1% rule as the maximum rate for taxation. The League for Direct Legislation secured the initiative and the referendum, the liquor interests a licensing system. Many of the amendments expressly enlarged the powers of the General Assembly. Several sought by the labour element were intended to spur the Legislature to action for industrial and social betterment. Amendments affecting the judiciary and the jury system were designed to expedite the work of the courts. A home-rule amendment gave the cities freedom to adjust themselves to the new economic conditions. The old rule that amendments to be ratified must be approved by the majority of those voting in the election gave way to a new one requiring only a majority of those voting on the amendment. An attempt in 1913, following the convention of 1912, to introduce the short ballot by making a large number of state, county and township officers appointive, failed. In 1918 the effort which had continued for nearly 50 years to give the Legislature power to classify property for taxation was approved by the people, only to be declared unconstitutional by the courts, on a technicality. At the same time, on the eve of Federal prohibition, an amendment incorporated state prohibition in the state constitution.

More significant of the purpose to adapt state government to the needs of the time is the legislative history. In 1909 Ohio had the customary administrative system composed of special boards, commissioners, bureaus and departments created to meet special problems as the Legislature had recognized them, but with overlapping jurisdiction and uncertain responsibility. In hardly any respect was the state service adequate or modern. In charge of the charitable and penal institutions, for example, were 18 or 19 separate boards, competing for support, maintaining as many accounting systems, failing wholly in coördination. Successive Legislatures took up during the following decade the problem of reorganization. For a time, chiefly during the years 1909–15, the legislators seemed to be working towards a commission type of administrative organization. Then followed a period of hesitation in which party politics interfered with progress, 1915–7. The third stage of opinion, following 1917, strongly favoured a single executive officer, appointed by the governor.

A law of 1910 centralized the taxing power in a small State Tax Commission, bringing to an end an expensive system of decennial boards of equalization. The following year all the charitable and penal institutions were placed under a Board of Administration. Four commissioners took the place of 57 trustees. A single fiscal agent replaced 19 stewards. In 1911 the old Railroad Commission became the Public Service Commission. In this case, largely for personal reasons, the duties of state commissioner of railways and telegraphs, created in 1867, had been transferred to a commission of three members (Act of 1906). The law of 1911 gave the Public Service Commission the same power over public utilities in general which the Railroad Commission had had over railways and telegraphs. In 1913 the Legislature changed the Public Service Commission to a

Public Utilities Commission. The duties of the commission were redefined, emphasizing the procedure in the valuation of property and the determination of the reasonableness of rates and charges for public utilities. At the same session of the General Assembly a State Industrial Commission of three members was created to assume the functions of the Board of Awards in industrial accidents, the Bureau of Labor Statistics, the Bureau of Mine Inspection, the Department of Inspection of Workshops, Factories, and Public Buildings, the Board of Examiners of Steam Engineers, and the Board of Arbitration, together with the new duties of regulating hours and conditions of labour. This Act was a part of the legislative progress of industrial insurance in Ohio. In 1911 the Workmen's Compensation Act had substituted "a system of compensation for industrial accidents, which compensation is to be paid out of a state insurance fund, to which both employers and employees contributed (90% and 10% respectively) in lieu of the civil action for damages." This first plan of state insurance was optional. The Act applied only to employers with five or more employees. A State Liability Board of Awards, with one member representative of labour, one of employers, and another of the public, was created to administer the system of compensation. The law of 1913 made the system compulsory. Employers were required to guard the safety of employees and also to arrange reasonable hours of work. Employers with less than five employees might take out workmen's insurance and have the benefit of the cheap state rates and of the protection from civil suits for damages which the system gives the employers. Ohio under the Act maintains its own state insurance fund. Every employer pays into the fund an amount proportioned by the State Industrial Commission to the amount of the pay-roll and the hazards of the occupation. The employer may carry his own compensation insurance, but in that case he must give the state a bond. By 1918 the premium income to the state fund amounted annually to $9,000,000. At a cost of 4½% of the premium receipts the Industrial Commission gave protection to more than 1,500,000 workmen.

In the days when the interests of Ohio were chiefly agricultural there were three especially important institutions: the Department of Agriculture, the State Experiment Station and the College of Agriculture. There was, however, confusion regarding the specific duties of each, and duplication of work. To remedy this the reform Legislature of 1913 brought the three institutions, together with the dairy and food commissioner and the fish and game commissioner, under a small agricultural commission with four members. Two years later, with a change of administration, the Legislature undid the reform in part, making the Experiment Station and the Agricultural College independent institutions, and restoring the large Board of Agriculture of 10 members without a salary. A change in political parties occurred again in 1917 and the Legislature, while retaining the large Board of Agriculture, made its functions those of an advisory council. The position of Secretary of Agriculture was created, and responsibility put upon him as director of the department.

The same type of organization was applied in 1917 to education and health. There had been an elective state commissioner of common schools since 1853. One of the constitutional amendments of 1912 instructed the Legislature to make provision for a state-wide public-school system, and substitute for the commissioner elected by the people a superintendent of public instruction, appointed by the governor. The Legislature appointed a special commission to survey the needs of the rural schools and in 1914 enacted a Rural School Code; three years later it created a State Board of Education. A state superintendent of public instruction appointed by the governor became secretary and executive head. The reorganized Department of Education was instructed to emphasize rural agricultural education, and to coöperate with the Federal Government in vocational education. The old State Board of Health was at the same session subjected to a similar reform. In caring for the health of its people Ohio had been notoriously backward. Successive legislative Acts increased the power of the State Board of Health and prepared the public mind for the reorganization of 1917–9. In the Act of 1917 a State Commissioner of Health was supported by an Advisory Public Health Council of four members. The statute of 1919 created a state-wide system of municipal and general health districts. Cities of 25,000 constituted municipal health districts; townships and smaller cities general health districts. The law provided for local commissioners of health and an Advisory Council modelled on the state organization. The powers of the Department of Health were greatly increased, and each district received power to employ physicians and nurses so far as necessary to protect the health of the community. The interest in roads led the General Assembly in 1915 to create a State Highway Commissioner. The following session of the General Assembly added a State Highway Advisory Board to serve without compensation. An Act of 1919 established a state highway levy of 5/10 of a mill per $100, and authorized the development of a state system of highways and coöperation with the road-making enterprises of the Federal Government.

With a change of administration in 1921 the further reorganization of the state system of administration was made the principal policy. An Act was passed which combined the numerous departments and commissions which had grown up in recent years by legislative enactment into nine departments—finance, commerce, public works, agriculture, health, industrial relations, examinations, education and public welfare. At the head of each is a director, appointed by the governor. Each director is authorized to appoint, with the governor's approval, a purely advisory board. If the Act stands the test of constitutionality Ohio will have a system of administration analogous to that of the Federal Government. The state directors of departments correspond to the heads of the national departments. The secretary of state, auditor, treasurer, and attorney-general are still elected by popular vote. A change in the method of choosing them can only be made by a constitutional amendment, although in some cases the Act of 1921 transferred their duties to the new departments.

The General Assembly of 1913 authorized civil service reform and a budget system. A civil service commission of three, subsequently reduced to two, was established. Another statute authorized a commission or commissioner of budget, but made no direct specifications regarding the organization. From 1914 to 1921 there was a budget commissioner, and the foundations of modern budget procedure were laid. In 1917 the governor presented his budget to the Legislature, meeting both Houses in joint session and explaining the items of the budget and answering questions from the floor. Other progressive legislation included a children's code (1913), providing a state-wide juvenile court and a mothers' allowance system, and a pension system for teachers in the public schools (1919), supported in part by contributions from the teachers and in part from the school boards.

A disastrous flood in 1913, affecting especially the inhabitants of the Miami, the Scioto, and the Muskingum river valleys, led to a most thoroughgoing measure for the protection of the river valleys from future damage of the kind. The following session of the Legislature authorized the inhabitants of a danger area to form themselves into a "conservancy district" and appoint a "conservancy board" which should have adequate powers to secure funds by assessing the property of the affected area and to carry out such measures of protection as the board might adopt. By 1921 the Miami Conservancy District had practically completed a series of dry reservoir dams costing $25,000,000. The flood of 1913 cost more than 500 lives and in property an amount estimated from $250,000,000 to $350,000,000. At an expense of one-tenth of this amount one of the three valleys most liable to damage has removed the menace.

The municipal home-rule amendment of 1912 gave cities of over 5,000 inhabitants the privilege of adopting charters with very large powers of local self-government and with a great degree of freedom from legislative interference. The chief limitation was the failure to give the cities home-rule in levying taxes or in incurring debts. The state reserved the control of elections, of education, of the general police powers and all matters affecting the welfare of the state as a whole. However, the courts of Ohio have liberally interpreted the amendment so that the cities came into the possession of a really broad grant of local autonomy if they chose to claim it. Of the 82 cities qualified to adopt home-rule charters about one-fourth had done so by 1921. Fourteen—Akron, Ashtabula, Dayton, Cleveland, Cleveland Heights, East Cleveland, Gallipolis, Lima, Painsville, Sandusky, South Charleston, Springfield, Westerville, and Xenia—had adopted the city-manager plan of municipal government.

In order to mobilize more effectually the war resources and to aid the war policies of the national Government after the entry of the United States into the World War, the governor appointed, June 1 1917, an Ohio branch of the Council of National Defense. It constituted a sort of governor's cabinet on the war, although without legal status. It worked through committees of finance, food conservation, labour and industrial relations, publicity, transportation and the like. A state employment service, organized before the war, performed the important war task of supplying labour for the construction of the cantonment at Chillicothe. As many as 2,760 men were furnished within 24 hours. The total number of men furnished by the state to the army, navy and marine corps was 200,293; the number of deaths 4,982; the amount raised in Liberty and Victory loans $1,324,545,750.

Recent governors have been Judson Harmon (Dem.), 1909–13; James M. Cox (Dem.), 1913–5 and 1917–21; Frank B. Willis (Rep.), 1915–7; Harry L. Davis (Rep.), 1921– . (E. J. B.*)

**OHNET, GEORGES** (1848–1918), French novelist and man of letters (*see* 20.35), published in 1908 *La Route Rouge* and in 1912 *La Serre de l'Aigle*. His last work was *Journal d'un Bourgeois de Paris pendant la Guerre de 1914* (1914). He died May 5 1918.

**OHRWALDER, JOSEPH** (1856–1913), Roman Catholic missionary, was born at Lana, near Meran, Tirol, May 1856. In 1880 he went out to the Sudan as a missionary, and was in 1882 taken prisoner by the Mahdi. In 1892 he managed to escape, and the same year published an account of his experiences under the title of *Ten Years' Captivity in the Mahdi's Camp*. He died at Omdurman Aug. 8 1913.

**OKLAHOMA** (*see* 20.57).—The pop. of Oklahoma in 1920 was 2,028,283; in 1910 it was 1,657,155; an increase of 371,128 or 22.4% as compared with 866,764 or 109.7% in the preceding decade. The urban pop. increased from 19.3% of the total in 1910 to 26.6% in 1920. During the same period the density of pop.

increased from 23·9 per sq. m. to 29·2. Indians decreased from 74,825 to 57,337. Negroes increased from 137,612 to 149,408. The pop. in 1920 of the larger cities of the state was:—

| | | | |
|---|---|---|---|
| Oklahoma City | 91,295 | Bartlesville | 14,417 |
| Tulsa | 72,075 | Ardmore | 14,181 |
| Muskogee | 30,277 | McAlester | 12,095 |
| Okmulgee | 17,430 | Guthrie | 11,757 |
| Enid | 16,576 | Sapulpa | 11,634 |
| Shawnee | 15,348 | Chickasha | 10,179 |

*Industries.*—The most interesting fact in connexion with the state between 1910 and 1920 was the development in the production of oil and gas. In 1920 there were 25,000 wells producing either oil or gas or both, and 36 counties were classed as oil and gas producers. Tulsa is the centre of the oil and gas area of the state. Its pop. increased from 18,000 in 1910 to 72,075 in 1920. The production of oil increased from 52,028,700 barrels of crude oil in 1910 to 103,087,420 barrels in 1920, and its value from $19,227,000 in 1910 to $347,355,445 in 1920. In 1920 Oklahoma produced 3,900,000 tons of coal, 70,000,000,000 cub. ft. of gas, 130,950,500 lb. of lead, 6,275,560,500 lb. of zinc, and 125,500 tons of gypsum. The total value of Oklahoma's mineral products increased from $33,000,000 in 1910 to $400,000,000 in 1920. Of almost equal importance was the increase in the value of agricultural products. In 1909 the total value of all crops was $131,522,220, in 1919 it was $549,249,277; but, due to the drop in prices, in 1920 the total value was only $294,715,000. Corn, cotton, live stock and wheat are the most important farm products. The growth of manufacturing also has been large. The chief industries are the manufacture of flour and meal, smelting, oil-refining, and meat-packing. The following table prepared by the U.S. Census Bureau gives a comparative summary for 1914 and 1919:—

| | 1919 | 1914 |
|---|---|---|
| Number of establishments | 2,445 | 2,518 |
| Proprietors and firm members | 2,320 | 2,464 |
| Salaried employees | 6,491 | 2,793 |
| Wage-earners | 29,503 | 17,443 |
| Capital | $277,034,318 | $ 65,477,654 |
| Salaries | 11,961,191 | 3,202,332 |
| Wages | 35,025,942 | 11,011,043 |
| Cost of materials | 312,605,829 | 70,969,750 |
| Value of products | 401,362,869 | 102,005,693 |
| Value added by manufacture | 88,757,040 | 31,035,943 |

*Education.*—During the decade 1910–20 great progress was made in education. The public schools employed 8,315 teachers in 1910 and 15,711 in 1920. The number of teachers holding first-grade certificates increased from 2,095 to 9,906. The enrolment of pupils in 1910 was 415,116, in 1920 it was 589,282. The number of graduates from the eighth grade increased from 3,725 in 1911 to 11,465 in 1920. The number of accredited four-year high schools increased from 29 in 1912 to 269 in 1920. The total expenditures for public schools in 1910 were $8,600,450.32 as against $22,826,947.57 in 1920. Similar growth has been shown in the higher educational institutions supported by the state. The six state normal schools, the Agriculture and Mechanical College and the secondary agricultural schools, as well as other state secondary schools, have made progress. The university of Oklahoma, which in 1907–8 had 40 instructors and 790 students, had in 1920–1, 215 instructors and 3,965 students, inclusive of the summer session, but exclusive of correspondence and extension work. In 1916 the Industrial Institute at Chickasha was reorganized and renamed the Oklahoma College for Women; it is the only school maintained by the state that is not coeducational. The following colleges are maintained by their respective churches:—Kingfisher College, Kingfisher (Congregational); Oklahoma City College, Oklahoma City (successor to Epworth; Methodist Episcopal); university of Tulsa, Tulsa (Presbyterian; formerly Henry Kendall College); Phillips University, Enid (Christian); Oklahoma Baptist University, Shawnee (Baptist); Oklahoma Catholic University, Shawnee (Roman Catholic). The following junior colleges are maintained by church interests:—Oklahoma Catholic College for Women, Guthrie; Oklahoma Nazarene College, Bethany; Oklahoma Presbyterian College for Girls, Durant.

*History.*—In 1910 the state capitol was moved from Guthrie to Oklahoma City. In 1913 an effort to move it back to Guthrie was defeated by popular vote. The state adopted in 1910 an election law designed to keep negroes from voting. This law contained the "Grandfather Clause," but was declared unconstitutional by the U.S. Supreme Court in 1915. In 1918 an amendment to the constitution was adopted granting equal suffrage to women. The state steadily maintained a law guaranteeing depositors in state banks against loss. This law has been so far successful that not a single depositor has met loss through the failure of a state bank. At the time of its admission in 1907 Oklahoma contained more than one-third of the Indian population of the United States. These Indians came from numerous tribes that had been moved to Oklahoma in the 19th century. The absorption of the Indians into the general body of citizens has gone on increasingly since 1910. The Indians of Oklahoma had by 1920 practically no separate history, and such tribal organizations as were maintained were not for governmental purposes but were business corporations for the control of tribal property. The great mineral wealth of Oklahoma has made many of the Indians extremely wealthy. The Osage tribe in particular continued to hold much of its land as tribal property, and its members receive very large royalties. This was not true of certain other tribes, as the lands assigned to them are valuable only for grazing purposes, and the individual allotments under such circumstances bring small incomes.

The governors of Oklahoma after 1910 were:—Lee Cruce (Dem.) 1911–5; Robert L. Williams (Dem.) 1915–9; James Brooks Ayres Robertson (Dem.) 1919– .

BIBLIOGRAPHY.—Recent works on the history of Oklahoma include the following:—Joseph B. Thoburn, *The Standard History of Oklahoma* (1916); Roy Gittinger, *The Formation of the State of Oklahoma* (1917); John Alley and Frederick F. Blachly, *Elements of Government with History and Government of Oklahoma* (1920). GI.)

**OKUMA (SHIGENOBU)**, MARQUESS (1838–1922), Japanese statesman (*see* 20.61). In the spring of 1914, the old statesman emerged, at the age of 76, from his retirement at the special behest of the Throne, to take up once again the reins of Government, as, owing to some unfortunate scandals arising out of a contract for a battleship, public confidence in Government probity had received a severe shock. The veteran guided the country safely through the opening months of the World War. In Dec. 1914, the Government suffered a defeat on the army estimates and the Diet was dissolved. Count Okuma himself conducted a vigorous election campaign, which resulted in a great triumph for the Government at the general election in March 1915. Charges of bribery at the elections were later brought against the Home Minister, Visct. Oura, with the result that a Cabinet crisis arose, and Count Okuma resigned on July 30. He was pressed to remain in office, however, and, finally consenting, constituted a new Cabinet on Aug. 10, temporarily taking over the portfolio for Foreign Affairs until this was accepted by Baron (afterward Visct.) Ishii. During 1916, treaties were concluded with France, Russia and China. On Oct. 3 1916, Count Okuma announced his intention to retire, owing to his failing health; and on Oct. 9, Marshal Terauchi formed a new Ministry. Previous to his resignation the Count received a marquessate, in recognition of his eminent services to the State, since the restoration, as a Genro or elder statesman. He died at Tokyo Jan. 10 1922.

**OLLIVIER, OLIVIER ÉMILE** (1825–1913), French statesman (*see* 20.89), died in St. Gervais-les-Bains (Savoy) Aug. 30 1913.

**OLNEY, RICHARD** (1835–1917), American statesman (*see* 20.91), died in Boston, Mass., April 8 1917. Because of his age he declined, in 1913, President Wilson's offer of the ambassadorship to Great Britain, and likewise in 1914 that of the governorship of the Federal Reserve Board. In 1915 he was a member of the International Commission created under the treaty between the United States and France, "looking to the advancement of the cause of general peace."

**O'NEILL, NORMAN** (1875– ), British musical composer, was born in London March 14 1875. He was educated in London and afterwards at Frankfort-on-Main. His compositions include songs and chamber music; much incidental music including that to *Hamlet* (1904); *A Lonely Queen, A Tragedy of Truth* (1906); an overture *In Spring Time* (Birmingham Festival 1906); *The Last Heir* (1908); *King Lear* (1909); *The Blue Bird* (1909); *The Golden Doom* (1912); *The Pretenders* (1912) and *Mary Rose* (1920). In addition to music for the theatre O'Neill wrote the overtures *In Autumn, In Spring Time, Hamlet,* a series of Miniatures for small orchestra and another for a large orchestra; a piano quintet, two piano trios, a Scotch rhapsody for orchestra; the ballad, for baritone solo and orchestra, *La Belle Dame sans Merci* and much instrumental music in the smaller forms. He edited *A Golden Treasury of Song,* and the *Ethical Hymn Book.*

**ONNES, HEIKE KAMERLINGH** (1853– ), Dutch physicist, was born in 1853. He studied mathematics and physics in his native town, Groningen, where in 1879 he took his doctor's degree on presenting a dissertation entitled *New Proofs of the Earth's Rotation.* He became professor at Leiden in 1882, and devoted himself especially to the study of properties of matter at low temperatures. As director of the Cryogeen Laboratory, founded by him at Leiden, he succeeded, in 1908, in liquefying helium. In 1913 the Nobel prize for physics was conferred upon him. His published work includes *Algemeene Theorie der Vloeistoffen* (General Theory of the Fluids, 1881).

See J. P. Kuenen, *De Toekenning van den Nobelprys aan H. Kamerlingh Onnes* (*Chemisch Weekblad*, 1913).

**ONTARIO** (*see* 20.113).—The area of this Canadian province was increased in 1912 by the addition of the district of Patricia, 146,400 sq.m. in extent, bringing the total up to 407,262 sq. miles. Ontario can now reckon 600 m. of seaboard along Hudson and James bays and over 1,600 m. of continuous fresh-water shore-line along the Great Lakes, bays and rivers to the south.

Old Ontario, which is subdivided locally into W. and E. Ontario, is the portion of the province S. of the Ottawa river and Lake Nipissing, lying between lakes Ontario, Erie and Huron. Northern or New Ontario is mainly a vast region of forests, mineral lands, rivers and lakes. It contains nearly 200,000 sq.m. of forests, abounding in game, rich in timber, and possessing incalculable resources of pulpwood, and it has already made Ontario an immense producer of minerals, although the resources of the country in this direction are still largely unexplored. New Ontario also possesses many millions of acres of fine farming land. Considerable districts are already well farmed, and have proved that this great northern country is well adapted for the production of general farm crops, dairying and the raising of live stock. At Kapuskasing the Ontario Government has established a soldiers' settlement scheme, and many veterans of the World War are making a success of farming on grants of 100 ac. given them free by the Provincial Government. The Timiskaming and Northern Ontario railway, 253 m. long, passes through the new country from North Bay to Cochrane.

The pop. was 2,523,274 (1,299,290 males and 1,223,984 females) in 1911; and, according to estimate, 2,799,000 at the beginning of 1919. Nine-tenths of the pop. lives between the Great Lakes, the Ottawa and the St. Lawrence, and more than half is urban. The Indian pop. numbered 23,044 in 1911.

*Government.*—The lieutenant-governor is assisted by an Executive Council whose members have seats in and are responsible to the local single-chamber Legislature, which is made up of 111 members elected by universal suffrage. Ontario sends 24 senators and 82 members of the House of Commons to the Parliament of Canada. The Conservative Government of 1905 and 1908 was again successful in the general elections of 1911 and 1914, being returned with a majority of 60. Upon the death of Sir J. P. Whitney in Sept. 1914, shortly after the war broke out, Mr. (afterwards Sir) William Howard Hearst succeeded as Premier. His Government was badly defeated in Aug. 1919. The defeat was attributable to two things: the decision of the farmers of Ontario to organize for political purposes under the name of the "United Farmers of Ontario," whereby Sir William Hearst lost practically the whole of his rural support, and the defection of many of his Conservative supporters on account of the passing of the Ontario Temperance Act. The "United Farmers of Ontario" grew to extraordinary proportions during the years 1919 and 1920, embracing practically the entire agricultural population, and became one of the most distinct phases of modern political tendency in recent years. The movement has extended to practically all the other provinces of the Dominion. In the elections of 1919 the successful U.F.O. candidates, in alliance with Labour members, formed the dominant group in the Legislature so that the subsequent Government of Ontario was known as "the Farmers' Government." The municipal system, though based rather on the simple English model than on the more complicated municipal governments of the United States, has certain features of its own, and is revised from time to time. The principle of municipal ownership was not readily accepted in the larger cities, and for long the powers of certain large corporations tended to cause friction, but such matters as the provision of electric power and light and traction have been gradually taken in hand both by the municipalities and by the province. The Hydro-electric Commission of Ontario, which controls a system of electric railways and power and light for a large portion of western Ontario, is a striking example of the tendency towards municipal government and ownership and control of public utilities. During the nine years before 1921, the operations of the Commission rapidly extended, and in 1919 about 143 Ontario municipalities derived electrical power from the Niagara Falls and other sources. The total cost of the plant erected was $20,077,491; the cost of operations for the year 1917 was $5,077,491; and the revenue was $6,070,065, leaving a surplus of $992,574, less a depreciation charge of $607,206, making the net surplus $385,368. The total number of consumers in 1917 was 170,916 and the total taken was 157,043 H.P. for 143 municipalities. Large additions were made to the scope of the Commission after 1917, and in 1921 many extensions were in contemplation, the whole question being under investigation by a Royal Commission.

Toronto, the capital of the province, is the chief manufacturing city of Canada. Ottawa is the capital city of the Dominion. Of the other principal towns of Ontario, Hamilton had a pop. of 108,143 and London 59,100 in 1919.

*Education.*—As in other provinces, education in Ontario is controlled by the Provincial Government and admiaistered by a Minister of Education with a subordinate staff. The cost of public education in Ontario increased from $4,720,310 in 1901 to $14,111,835 in 1918. In 1917 there were 6,651 public schools providing free education, which between the ages of 6 and 16 is compulsory. There were 12,762 teachers with 527,664 pupils. The falling-off in the rural population of Ontario caused a corresponding diminution in school attendance, but this has been more than compensated for by the rapid growth of the cities. Although many Roman Catholic children attend the public schools the number of separate schools is steadily increasing. Government inspectors visit these schools (of which the teachers must be certificated), and keep them up to legal standard, but are not concerned with religious teaching.

The university of Toronto, with its affiliated colleges, had in 1918 a staff of 525 and 3,356 students, and in the faculty of applied science and engineering alone had seven distinct departments. The number of students in all the universities greatly increased after the close of the war.

*Finance.*—The indebtedness of the province has shown a tendency to increase. It began with the construction of a provincial railway to aid in the development of the northern districts; and more recently costs incidental to the World War, the building of roads under a good-roads system aided by the Dominion Government, the extension of the schools system, housing and other modern improvements have greatly increased the public liabilities. A large share of the burden of local administration is borne by municipalities. Revenue and expenditure were respectively $11,121,382 and $11,819,311 in the financial year 1913–4 and $19,870,123 and $17,460,404 in 1917–8.

*Agriculture.*—Ontario is, above all, the province of Canada where agriculture has been most scientifically carried on, and the greatest results achieved. The total area under field crops in Ontario in 1918 was in round figures 10,000,000 acres. A much larger area of good land is actually owned and occupied, and in northern Ontario there were 20,000,000 ac. of virgin agricultural land as yet untouched. The market value of the 1918 crop was $384,000,000; oats, wheat, barley, peas, beans and corn were the principal yield. Grain-growing, however, by no means represents the whole field of agriculture in Ontario. Mixed farming and dairying in all its branches are really the backbone of the industry. Ontario produces practically half the butter and cheese made in Canada. The annual output of the cheese factories is approximately 120,000,000 lb. valued at $25,300,000, while the creameries manufacture upwards of 28,000,000 lb. of butter valued at $11,000,000. To this must be added the dairy butter, milk powder, condensed milk and milk used for city trade, the total annual value of which is approximately $50,000,000. There are 990 cheese factories with 42,066 customers and 172 creameries with 45,944 customers. The Provincial Government's staff of dairy instructors maintains a uniform high standard of output from all factories and creameries. Immense quantities of butter and cheese are exported annually.

The live-stock industry of Ontario is very important, and some of the best horses, cattle and sheep on the continent are raised in the province. The official reports showed that there were in 1920 in Ontario 732,977 horses, 2,872,722 cattle, 972,541 sheep and lambs, 1,656,386 swine, and poultry to the number of 12,271,105. In the Niagara fruit belt, and along the shores of Lake Erie, Ontario possesses one of the most beautiful and fertile fruit-growing districts

in the British Empire. The manufacture of wine from native grapes is one of the flourishing industries of this belt. Tobacco is extensively grown in the counties of Essex and Kent along Lake Erie where the soil and climate are found to be suitable, and tobacco grown from the right varieties of seed is pronounced to be comparable with that of the southern states. Most of the tobacco raised is manufactured within the province for home consumption but an effort is being made to reach the British and other markets. The cultivation of sugar beet is also becoming of importance and large sugar refineries are located at Chatham and elsewhere. The yield in 1919 was 240,000 tons, the product of 24,500 acres. The area of sugar-beet growing constantly tends to expand. The growing of flax, both for seed and fibre, is attracting a good deal of attention.

In addition to the "United Farmers of Ontario," the objects of which are primarily political, many active organizations are maintained by the farmers themselves to advance the interests of the agricultural community, including the Ontario agricultural and experimental unions, farmers' institutes, women's institutes, coöperative societies, etc. The provincial department of agriculture also maintains a corps of district representatives, all skilled agriculturists resident at important farming centres, whose whole time is devoted to assisting the farmers. In the year 1919 the yield and value of the principal field crops in Ontario were as follows: wheat, 20,698,500 bus., $40,701,000; oats, 78,388,000 bus., $71,378,000; barley, 13,803,000 bus., $17,215,000; rye, 2,219,000 bus., $3,279,000; peas, 1,818,500 bus., $4,180,000; beans, 288,500 bus., $1,039,000; buckwheat, 4,072,000 bus., $5,534,000; mixed grains, 19,735,300 bus., $26,672,000; corn (maize), 15,152,500 bus., $18,790,000; potatoes, 15,145,000 bus., $20,820,000; turnips, etc., 42,756,000 bus., $14,027,000; hay and clover, 5,589,000 tons, $115,161,000; fodder corn, 4,414,000 tons, $25,304,000; alfalfa, 314,400 tons, $6,351,000; sugar beet, 241,000 tons, $2,606,000.

*Forests.*—Although Quebec has larger timber areas, the lumber industry of Ontario exceeds that of any other portion of Canada. The forest lands are estimated at 200,000 sq. miles. There are great areas of white pine, and of almost equal value with the making of pulpwood are spruce and poplar trees which occupy large districts in northern Ontario. The total amount of red and white pine still standing on lands belonging to the province exceeds 12,000,000,000 ft., while there are more than 350,000,000 cords of pulpwood on lands still in the hands of the Government. The largest pulp mill in the world is in operation at Sault Ste. Marie, and many others, almost equally large, are scattered over the northern section. Other valuable trees which are still plentiful are oak, beech, maple, elm and basswood; the whole of Old Ontario in its primitive state was heavily forested with these trees. The most important lumbering districts are on the upper Ottawa, west of Lake Superior and north of Georgian Bay, and the finished lumber not only finds a large local market but has a wide foreign distribution. Ottawa is still the most important lumber centre of the province. The Provincial Government recognizes the necessity of forest protection and reafforesting. Fire rangers patrol the forest during the summer and fall and five great areas, with a total extent of 17,860 sq.m., have been set apart as reserves for timber conservation and the preservation of water-supply. Algonquin Park, 2,000 sq. m. in extent, set apart as a national park, also contains valuable uncut timber.

The quantity of timber cut in Ontario in 1918 was 1,110,062,000 ft., valued at $34,168,754. Although the quantity cut was less than that in British Columbia, the value exceeded it by nearly $6,000,000. Over 52 % of the output was white pine, 11 % hemlock, 8 % red pine and about 6 % spruce. The returns made to the Dominion Bureau of Statistics in 1918 by 603 milling firms showed that the capital invested in logging plants amounted to $6,697,923 in land, buildings, machinery and tools, and in mills $10,527,006. The value of materials on hand was $18,846,365; cash trading and operating accounts $10,791,050, making a total capital employed of $46,862,344. The Ontario mills employed 16,804 persons in the manufacture of lumber, to whom $12,926,710 was paid in wages. In the same year the pulp-mills made for sale pulp to the value of $9,711,840 and the pulp and paper mills made 312,459 tons of pulp for their own use, total output of pulp being valued at $13,613,639. The value of all kinds of paper produced in 1918, including news-print, book and writing paper, wrapping-paper, boards and other products was $63,908,247. About $46,000,000 of this was for news-print alone.

*Fisheries.*—The fresh-water fisheries of the province, including the Great Lakes and the Lake of the Woods and Lake Nipigon, are extensive and valuable. The principal fish caught are herring, whitefish and trout, but the catch also includes pike, pickerel, dore, sturgeon, eels, perch, tullibee, catfish, carp and coarse fish. The fisheries of the province are under Dominion regulation and provincial control. For the purpose of restocking the waters and increasing the fish supply the Dominion Government maintains several fish hatcheries. A promising new field lies in the rich fisheries of Hudson Bay which have not yet been developed owing to lack of transport facilities. The total value of the catch for Ontario in 1919 was $3,410,750 and included herring $657,042; mixed fish $134,312; perch $152,440; dore $259,470; pickerel $167,419; pike $139,636; trout $772,174; whitefish $857,492.

*Mining.*—Ontario, originally almost exclusively an agricultural province, has taken the lead in mineral production, the output for 1919 being valued at about $66,000,000, almost double that of British Columbia (which formerly stood at the head of the list), while the output for 1918 was valued at as much as $94,694,093. Almost all the economic minerals are found except coal.

The mining of the silver ores discovered at Cobalt in 1903 reached its greatest activity about 1912. Shipments from the camp and outlying silver areas up to Dec. 31 1918 were 292,385,866 oz., valued at $169,292,351. The total figures for the province in 1918 showed an output of 17,738,153 oz., valued at $17,415,882, and in 1920 5,308,852 ounces. As far back as 1896 the occurrence of gold in the Porcupine district, the prospecting of which was a natural outcome of the explorations in Cobalt, was noted by Government surveyors, but the district was not seriously considered until the spring and summer of 1909, when prospectors rushed to the district. By 1910 the country for miles around was staked and recorded, and the producing stage was soon reached. For 1918 the output of the province was 411,878 oz., worth $8,502,480—the largest in the Dominion—and for 1920, 564,959 oz., 73·7 % of the total in Canada.

It was expected in 1921 that the tributary regions E. and W. of the chief existing mines would prove to be amongst the richest in the world. The nickel mines at Sudbury constitute the most important source of supply of this metal. Copper is mined in the same district in large quantities. A large iron-mine is located at Michipicoten and there are iron and steel works at Midland, Deseronto, Hamilton, Sault Ste. Marie, Port Arthur, Owen Sound and Ottawa. Corundum occurs in the townships of Farrday, Dunganan, Monteagle, Carlow, Ragland, and adjacent townships of Hastings and Renfrew counties in southern Ontario, and within the Haliburton–Bancroft area. There are many gas-producing wells in Ontario, the principal fields being, in order: Welland county, Haldimand and Norfolk, and Essex and Kent. Practically the whole output of petroleum in Canada is produced in Lambton county and from the newer oil-fields of Mosa, Tilbury, Romney, Bothwell, Leamington, Dutton, Thamesville, Comber and Onondaga townships in the extreme south of Ontario. The four chief oil refineries belong to the Imperial Oil Co., Sarnia; the Canadian Oil Co., Petrolea; the British-American Oil Co., Toronto; and the Empire Refining Co., Wallaceburg. There are extensive salt deposits in the western part of the Huron–Erie peninsula, some of great thickness. Salt is produced at Windsor, Sarnia, Golderich, Kincardine, Wingham, Stapleton, Elaston, Exeter and Parkhill. Feldspar, graphite, marble, quartz, pyrites, granite, sodalite, talc and zinc, as well as clay and its numerous products, together with limestones and excellent sandstones, are among the mineral resources.

In 1919 the statistics of mineral production were as follows:—gold, 505,964 oz., value $10,451,709; silver, 11,363,252 oz., $12,904,312; nickel, 22,035 tons; copper, 12,099 tons; iron ore exported, 5,953 tons; pig-iron (from Ontario ore only), 46,769 tons, $1,200,793; total pig-iron, 632,586 tons, $16,010,537; portland cement, 2,022,575 bar., $3,659,720; petroleum, 7,703,515 gal., $632,789; natural gas, 11,085,819 mill. cub. ft., $2,583,324; salt, 148,112 tons, $1,395,368.

*Manufactures.*—With abundance of raw material, cheap power and ample facilities for transport Ontario has come to be the chief manufacturing province in the Dominion. The chief products are iron and steel machinery, electrical apparatus, agricultural implements, carriages, wagons, automobiles, pianos, organs, flour, oatmeal, pulp, paper, furniture, woollen and cotton goods, clothing, sugar, wire fencing, paints, leather goods, boots and shoes, carpets, cement, canned goods, glass, biscuits, confectionery, and meat products. Nearly every village and town has its manufacturing plant of more or less importance, but the chief industries are concentrated in the larger cities like Toronto and Hamilton. In 1918 15,337 industrial establishments with a capital of $1,442,221,000 employed 320,808 hands and paid $302,399,000 in salaries and wages. Raw materials cost $905,153,000 and the products were valued at $1,640,772,000.

*Communications.*—One of the national lines of railway passes through the northern part of the province, opening up the Clay Belt for settlement and cultivation. A branch connects the main line with Port Arthur. Running north from North Bay the Timiskaming and Northern Ontario railway, 253 m. long, owned and operated by the Provincial Government, joins the national line at Cochrane. In addition to the steam railways there are hundreds of miles of electric lines running through the rural districts, connecting the principal towns and cities. With the development of electrical power more and more such railways are being built, mainly under municipal ownership.

Apart from the great highway of the St. Lawrence, the Rideau canal between Ottawa and Kingston, the Trent Valley canals from Trenton through the Kawartha Lakes to Georgian Bay, and the Murray canal separating the peninsula of Prince Edward county from the mainland are of high commercial importance to Ontario.

(W. L. G.*)

**OPTOPHONE.**—The optophone is an instrument for enabling totally blind people to read ordinary letterpress, such as a printed book or newspaper, without the necessity of printing it in raised type to be read by touch. The instrument was

invented in 1914 by Dr. E. E. Fournier d'Albe, then a lecturer in physics in the university of Birmingham. It is based upon the properties of selenium, an element which is a better electrical conductor in light than in darkness. A beam of light is rendered intermittent by the interposition of a revolving siren disc and is then concentrated into a small bright point on the paper to be read. If the point on the paper is white, it will reflect the light; if it is black it will not. A selenium cell placed close to the paper, on receiving the reflected beam of intermittent light, will respond to each flash by a change in conductivity, and if the frequency of the flashes is of the "musical" order (between 30 and 30,000 flashes per second), a telephone receiver connected with the selenium and a battery will sound a musical note. A blind person could thus tell whether the paper is black or white.

That is the principle of the optophone. In practice a small row of luminous points is substituted for a single point, and each point in the row is given a different frequency by suitably perforating the siren disc. The row, usually of five or six points, just fills up the size of the tall letters of the print to be read. When the whole row falls upon the black stem of a letter there is silence in the telephone. As the letters pass their various shapes are indicated by the sounding or silence of the different notes, and after some practice the blind person learns to recognize letters from their sounds, and so to read ordinary type.

The first reading test was given by the inventor in March 1917, the matter read being a leading article in *The Times*. In Aug. 1918, Miss Mary Jameson, a blind pupil from Norwood, gave the first public reading demonstrations, reading an unknown page from a book at a speed of about two words per minute. Later, with an improved instrument, she attained a speed of about 20 words per minute. A new type of optophone was brought out in 1920 by Barr & Stroud, of Glasgow. In this instrument two selenium cells were used, balanced against each other in such a manner that white paper produced silence, and the black letters themselves made the musical sounds. Reading demonstrations were also given with this instrument, but any advantage in the way of ease of reading was found to be counterbalanced by a greater delicacy and complexity of adjustment. The new type is known as the "black-sounder," and the original type is termed the "white-sounder." The latter type was approved by the Inventions and Research Committee of the National Institute for the Blind in 1921 after an exhaustive series of tests. The optophone is intended to place the world's printed literature once more within reach of the blind. It is applicable, without special preparation, to any language, and can also be used for reading typoscript, but not handwriting.

See "A Type-reading Optophone," *Roy. Soc. Proceedings* (1914); "The Optophone," *Journal of Roy. Soc. of Arts* (1921); "The Optophone," *St. Dunstan's Review*, No. 55 (1921).

(E. E. F. D'A.)

**ORANGE FREE STATE** (*see* 20.151), a province of the Union of S. Africa. At the 1911 census it had a pop. of 528,174 compared with 387,315 in 1904—an increase of 26·67%. Whites numbered 175,189, coloured 352,985. In 1918 the white pop. was 181,678. The increase in pop. since 1904 was very largely due to the development of agriculture and stock farming, the province being essentially a pastoral region.

The only big town is the capital, Bloemfontein (pop. in 1911 26,925). While new settlers included many of British origin, the white inhabitants remained predominantly of Dutch descent. Nearly all the coloured people are Bantu and in 1911 the province had only 108 Asiatics. A higher proportion, 50·77%, of the natives professed Christianity than in any other province of the Union.

There were in 1918 only 5,588 persons (all races and both sexes) engaged in factories in the province, but in Jagersfontein it possesses one of the chief diamond mines in S. Africa, and there is a group of small but rich diamond mines in the Boshof area, proclaimed in 1906, 1910 and 1912. There are coal mines by the Vaal at Vereeniging, which produced 469,000 tons in 1910 and 838,000 tons in 1919.

Dr. A. E. W. Ramsbottom was the first administrator, being succeeded by Mr. H. C. Wessels. Both had been members of the Ministry during the brief period (July 1907–May 1910) while the province had been a self-governing colony. The provincial administration at first continued the system of compulsory bilingual education enforced in 1908, but the struggle conducted by the English-speaking part of the people over the medium of instruction came virtually to an end in 1912, the provincial council having adopted, in the main though still with a bias in favour of the Dutch language, the proposal suggested by the Union Parliament that up to standard IV. instruction in the schools should be given in the "home language" of the scholar. In 1920 an ordinance was passed recognizing "Afrikaans," *i.e.* the Taal or colloquial Dutch, as equivalent to Netherlands Dutch as a medium of instruction, and its adoption, for Dutch scholars, was very general. In most respects the provincial administration was progressive and was conducted on non-party lines. (For the administrative system see CAPE PROVINCE.) Provincial expenditure rose from £511,000 in 1912–3 to £611,000 in 1917–8, the amount spent on education in the years named being £250,000 and £473,000 respectively.

The province was the stronghold of the Dutch Nationalists. Up to his death in 1916 ex-President Steyn, who lived near Bloemfontein, though he held no office, exercised very great influence on public affairs. In the crisis caused by the World War Steyn opposed operations against German S.W. Africa. There followed the rebellion of Gen. De Wet, the Free State being the principal theatre of the campaign. Gen. Hertzog, the parliamentary chief of the Dutch Nationalists and after Steyn's death their undisputed leader, carried the Free State in the elections of 1915, 1920 and 1921. In Feb. of the last-named year, when he had declared for the secession of the union from the British Empire, his party won 16 out of the 17 constituencies into which the province was divided (*see* SOUTH AFRICA).

(F. R. C.)

**ORDNANCE**[1] (*see* 20.189.)—(I.) PRINCIPLES OF DESIGN. The principal requirements from a gun are accuracy, high muzzle velocity and high remaining velocity at any given range. These points are dependent on the ballistics, or power, of the gun, on the twist and form of the rifling, and on other factors outside the gun, such as the weight and shape of the projectile and the design of the driving-band on the projectile.

At the same time as definite conditions are laid down for these main requirements, certain limitations are imposed upon the designer in connexion with the working pressures in the gun, the length and weight of the gun, the feasibility of repair, and the length and weight of the projectile. These various factors must be considered from the point of view of their relation to each other as they are to a very large extent interdependent, and variation in any one of them will react on one or more of the others. The limiting factor in the working pressure is the strength of the gun to resist the firing stresses, and any increase in these beyond a certain limit will necessitate a corresponding increase in the strength of the gun, that is, in the amount of material employed in its construction, which obviously entails an increase in the weight of the gun, a very important consideration. The length of the gun has an important effect on ballistics, and any increase in this respect not only is accompanied by increased weight but also affects the question of the space occupied, another important consideration. Further, any variation in the weight or length, or both, of the gun will affect the position of the centre of gravity, and so affect the design of the mounting or carriage. Another aspect of the question of length is its effect upon the "girder strength" of the gun. In modern ordnance efforts are made to place the centre of gravity as near the breech as possible, and, the gun being supported on its mounting at or near this point, with long guns a considerable proportion of the total length remains unsupported, and therefore has a tendency to "sag" due to its own weight. Theoretically a longer gun gives better ballistics, but in practice the length of modern guns is usually 45 to 50 calibres; though this has been sometimes exceeded in what may be termed "freak" guns, and may in future be exceeded in hyper-velocity

Vickers, Ltd.; the Editor of *Mechanical Engineering*; the Royal Carriage Department, Woolwich; the Royal Artillery Institution, Woolwich; and the U.S. War Department.

guns. The possibility of repair, when worn out, has considerable bearing on design, for where this is required the inner tube, or barrel, is made in two parts, one inside the other, so that when necessary the inner one can be removed and replaced. The British practice is that all guns, except very light guns, are built with an inner "A"-tube. The probable life of a gun is estimated by the number of rounds it can fire before being worn out and depends on many factors, the principal of which is the action of the powder gas. In the actual design it is affected by the material to be used for the inner tube and by the shape and size of the chamber.

*Problem of Design.*—The problem before the gun-maker is to build a gun under defined limitations of weight, etc., that will withstand certain definite pressures at various parts of the bore. Steel is practically the only material now used in gun construction; but there are several classes or kinds of steel, and experience has taught which particular class can be obtained and used for the various parts of the gun. In addition to considerations connected with the design of the gun proper, there are two important points which require to be considered and embodied, namely, ease and rapidity of loading and firing. These two points necessarily involve the determination of the kind of breech-mechanism and the class of obturation to be employed. The weight of the moving parts of the breech-mechanism has a serious bearing on the ease of manipulation; and the mechanical device chosen for opening and closing the breech and the complication of the mechanism for holding and firing the means of ignition regulate very largely the rapidity of the service of the gun.

*Carriages.*—An artillery carriage must be designed primarily to provide a support from which the gun is fired; but in some cases the carriage is required to perform also the function of transporting the gun to the firing position. The demand is, therefore, for either a fixed or mobile carriage; and in the latter case it is accepted as a necessity in modern mountings that the under-portion, or basic structure, should remain immobile on firing. Since guns vary greatly in calibre, power and weight, the mobility of the carriage and the method of draught adopted must vary accordingly, because the weight and size will be determined largely by the gun for which it is designed; but, consistent with the functions required of it, the weight of a carriage should be a minimum and its mobility a maximum. The ideal of providing the travelling as well as the firing support in the carriage of any mobile gun is possible of attainment only with light and medium guns, owing to the limitation in weight for travelling; and the various designs of mobile carriages are a direct outcome of the necessity for mobility of loads varying from about 2 tons upwards.

*Movements Necessary.*—From the firing aspect, the modern requirements of any carriage necessitate that the gun shall be laid (*i.e.* aimed) quickly and accurately without any movement of the basic structure, and that the basic structure shall remain completely immobile during firing. Thus any carriage must be designed to permit of three distinct movements of the gun:—

(*a*) A movement in the horizontal plane—termed "traverse"—to give direction to the gun. This movement is limited with all mobile carriages, due to the fact that the side stability of the carriage must be maintained. Generally, the heavier the gun and carriage, the more extended must the traverse be, in order to avoid the necessity for frequent realignment of the basic structure for changes of target. With fixed mountings it is obviously necessary to have very wide and, indeed in most cases, all-round traverse, and this is obtained, so far as the constructive limitations of the mounting permit, by mounting the superstructure upon a central pivot under its centre of gravity.

(*b*) A movement in the vertical plane—termed "elevation." The elevation permitted to a gun determines its range and is, therefore, a determining factor in the design of the carriage. In recent years, increased range has been obtained with existing ammunition by removing from new designs those constructive limitations which limited the elevation in earlier types. With guns, the maximum range is obtained at about 43° of elevation; and with hyper-velocity guns (muzzle velocity about 5,000 f.s.) at about 55° of elevation; with howitzers, elevations up to 70° may be required, to give steep angles of descent; while an anti-aircraft mounting should be capable of giving elevations up to 85 degrees.

(*c*) An axial movement of the gun—termed "recoil"—the reverse of which, the returning of the gun to the firing position, is termed "recuperation." The latitude it is necessary to allow here depends on the type of carriage. All mobile carriages require a relatively long recoil in order to maintain stability at the lower angles of elevation. With fixed mountings a long recoil is not so necessary, and the length is relatively short (being fixed at from 3 to 4 calibres), while the mounting itself is designed to withstand the resulting stresses, since conditions of stability do not arise.

*Design Elements.*—In the designing of a gun—system or "equipment" as it is called—the controlling elements depend upon the particular purpose for which the gun is required. The gun may be for a mobile mounting or for a fixed mounting. The mobile mounting may be horse drawn or tractor drawn, or it may be carried by pack transport.

So far as the gun for field equipments is concerned, it is immaterial to the design whether the traction is by horse or tractor or whether the mounting travels as an entity or in parts. The gun is nowadays designed for a long recoil, and in itself is employed as a shield for the vulnerable recuperator which is carried in a cradle below it,[1] and above which the gun recoils along slides. For light field guns, in the interest of rapidity of fire, obturation is generally by means of a metallic cartridge case, and percussion firing is always used. To enable extraction of the cartridge case, an extractor must be embodied in, and be worked by, the breech-mechanism. As regards the breech-block for guns firing fixed ammunition, this may be either of the swinging type or a sliding wedge; but if fixed ammunition be not used, the block must be a screw and the obturation effected by an obturator-pad in the breech-mechanism, since the only practical means of obturation with a sliding wedge is by use of a metallic cartridge case.

With pack transport, the weight a mule can carry is the determining factor in the design of the gun. After deductions for the weight of the saddle equipment, etc., about 250 lb. is all that can be allowed per mule for the gun. Since the gun must be heavier than that amount in order to obtain the required power, it must be designed to be transported in two parts which can be readily and easily put together with a gas-tight joint; and the breech-mechanism must be capable of being quickly detached and reassembled.

With fixed mountings there are not the same restrictions as with mobile mountings; but the breech-mechanism must be arranged so as to allow of the use of electric, as well as percussion, firing apparatus.

As regards carriages, from the travelling aspect, it has to be remembered that the weight influences the draught, and the draught influences the design of the carriage. The general travelling conditions are as follows. For *horse transport*, in the case of a reasonable degree of mobility and manœuvre, six light-draught horses should not be exceeded. For heavier loads, eight heavy-draught horses may be employed, as they would be rarely required to move faster than at a walk. Pole-draught is now used universally. It follows that the limiting weights are 2½ tons for light field equipments, and 6 tons for medium field horse-drawn equipments when assembled for travelling. For *pack transport* an equipment must be capable of being split up into loads (usually from 6 to 8) no one of which exceeds 250 lb., and in addition fulfil the same functions as a field carriage, when assembled. Other conditions besides the weight limit have to be taken into account in designing pack artillery equipments, *e.g.* the centre of gravity of the load as it lies on the pack-saddle should be as low as possible, for stability. For *tractor transport*, if the travelling weight exceeds 6 tons, tractors must be used. A load up to 12 tons can be travelled tractor-drawn as an entity on two axles, for 6 tons is the maximum average axle-load. The total load behind a tractor should not exceed 20 tons, and steering requirements limit the number of units in the train. If it be desirable to travel super-heavy equipments by road, they must be so designed as to be capable

[1] Most British guns of pre-war design, used in the World War, had the buffer and recuperator above the gun. In types designed during the war this practice has been given up.

of being dismantled and split up into loads to conform to the necessary conditions. For *railway transport*, the railway mountings must be of the standard gauge[1] and conform to the railway load-gauge, which imposes limits as to width, height and shape of load. Any mounting must be able to travel on a curve of 150 feet radius, which governs the total length. The total weight is not limited as such, but it is governed by the span over which it is distributed; it must be supported on such a number of axles that the maximum load per axle is not more than 19 tons; and the total load divided by the length of the wheel-base over the buffers is not more than 2¼ tons per foot run.

Practically all modern mobile carriages at present have as their basic structure a gun carriage—consisting of a pair of wheels, an axle-tree, a trail and a limber consisting of a box mounted on an axle and two wheels, provided at the rear with a hook for connexion to the trail-eye, and at the front with the draught fittings. This method of transporting mobile artillery is universally employed both with horse-drawn and tractor-drawn carriages which can be travelled as entities. At the present day, however, caterpillar mountings are in use or under experiment in many countries.

Regarded from the firing aspect, the requirements of a field carriage demand as extended a traverse and elevation as possible, consistent with the requisite mobility. The main general designs may be given as follows:—

*Three-Point Support Carriages.*—In the usual form of carriage, the firing system, resting on the ground by its two wheels and the point of the trail (which is secured by a tract spade embedded in the ground), forms a three-point support. To preserve the side stability of this type, the force of recoil must be nearly coincident with the centre-line of the trail; consequently only a relatively small angle of traverse—4° either way—is allowable. The amount of elevation possible is affected by the form of the trail.

*Four-Point Support Carriages.*—This is a modification of the three-point support, consisting in the use of a split trail, the halves of which can be splayed outwards to form two struts, instead of one, in the firing position. In effect, this type has two trails and gives the advantage of an extended traverse—20° each way—without change of position. The amount of elevation obtainable is controlled by the balance of the gun and its height above the ground.

*Temporarily Fixed Mountings.*—When a road-mobile carriage cannot be travelled as an entity, there is no need to retain the wheels as part of the firing support; consequently such carriages must have embodied in the design some arrangement to allow of large traverse—at least 30° each way—in order to obviate subsequent alignment of the basic structure. The basic structure consists in a platform temporarily secured to the ground with the superstructure mounted above it in such a manner as to be pivoted. The transporting carriages are designed to facilitate mounting and dismounting. Elevation is affected by the shape of the superstructure.

*Railway Mountings.*—These are super-heavy carriages travelled as entities but restricted to the use of a permanent way.

*Factors in Design of a Gun.*—The main object in the design of a gun is to ensure sufficient strength at all parts of the gun to withstand firing stresses, with a considerable margin of reserve strength to provide accidental abnormal pressures or deliberate increase of pressure that may subsequently be found necessary.

In the design two important principles must be observed—(1) the tube in actual contact with the powder gases must be relieved of all longitudinal stresses; and (2) the work must be distributed over all the various parts of which the gun is built up. The pressure developed when the gun is fired acts in all directions; therefore the force acting upon the face of the breech-screw is equal to that acting upon the base of the projectile. In order to give effect to (1) above, it is always arranged that the breech-screw shall not gear direct into the inner "A"-tube, but into one of the outer parts of the gun; the only longitudinal stress, then, to which the inner tube is subjected is that caused by the projectile passing along the bore. As regards (2) above, the longitudinal stress is transmitted from the breech-screw through the various intermediate parts to the jacket or outer part of the gun (fig. 1).

[1] During the war period numerous equipments were designed for employment on narrow-gauge lines, notably by the French. But these were not railway mountings in the true sense, as they did not both travel and fire from the line. Their transport to the narrow-gauge track might be either by road or by rail.

In the case of wire-wound guns, requirements of longitudinal and "girder" strength present certain difficulties, because the wire coils do not give any strength in the direction of the axis of the gun. The practice is to make the parts outside the wire take the whole of the longitudinal stress, while they take little part in resisting radial stresses. "Girder" strength, or stiffness, is provided by the inner tubes as well as the outer parts; but in all long guns, more especially when wire-wound, there is a tendency for the unsupported part to sag.

The radial stresses are taken by the inner tubes and the wire in wire-wound guns. Since these stresses are not equal at all points in the bore, it is necessary to arrange the wire-winding accordingly. The firing stresses are greatest in the chamber, and as the projectile travels along the bore they gradually decrease. With a heavy gun, the chamber-pressure is about 18 to 20 tons per square inch, while the muzzle-pressure is only from 5 to 7 tons. The greatest strength, therefore, is required over the chamber; the number of layers of wire is greatest at that part, and gradually decreases along the gun towards the muzzle. In addition to regulating the amount of wire, the tension at which the various layers are to be wound must be calculated; these winding tensions are so arranged that, when the gun is fired, the whole of the wire is, theoretically, equally stressed. In all designs the circumferential strength is calculated with a margin beyond any anticipated stresses; this "factor of safety" is usually between 1·5 and 2.

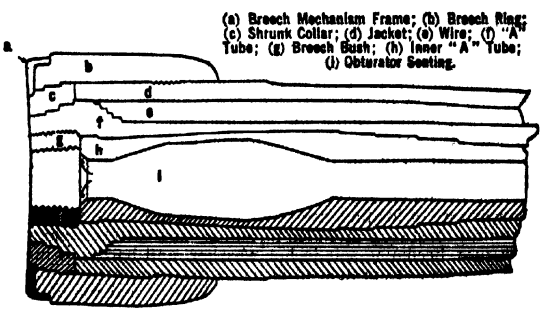

FIG. 1.—Breech end of B.L. 15-in. gun.

The longitudinal stresses are taken by the outer parts of the gun, viz. the jacket and "B"-tube, being transmitted to the former from the breech-screw through the breech-bush, shrunk collar and breech-ring. In order to provide for stretching of the inner "A"-tube and to prevent the formation of "steel-choke" in the bore, there must not be external shoulders, or steps, on this tube, except those at the rear end and immediately in front of the chamber which are provided to prevent bodily forward movement of the tube.

Further, the "girder" strength of the gun must prevent it from bending under its own weight when supported on its mounting, which normally affords support for only a small portion of the length near the breech end. For this reason the inner and outer tubes must be of sufficient thickness. Practically all tubes are of greater thickness than is theoretically necessary.

*Rifling.*—Exhaustive trials at various times have been carried out for comparing various systems of rifling for high-velocity guns. The general considerations are: the greater the number of grooves and the slower the twist the narrower can the lands be, owing to the reduced pressure on each driving edge of the grooves; shallow grooves weaken the bore of the gun less than deep grooves, but in a worn gun the latter allow the power of rotating a projectile to last longer; the broader the grooves in comparison to the lands, the greater the unengraved portions of the driving-band, and consequently the greater the resistance to shearing the band, with less danger of the band wearing smooth; the edges of the grooves should be normal to the surface of the bore so that the rotational pressure may be applied by the driving-edge at right angles to the radius of the projectile; the form of grooves should be as simple as possible, and the lower angles rounded to avoid any tendency for cracks to develop.

The form of groove in favour in Great Britain is a slight modification of the P.P.S. groove, so that the number of grooves per inch of

calibre is increased by 5–8, and the width of the grooves as compared with that of the lands is increased, the lands being reduced to the lowest limit necessary to withstand shearing. The advantages of this system are that less copper is cut away by the lands, thus leaving more to withstand the wear in rotating the projectile; and that the total bearing surface of copper against the lands is larger, due to the larger number of grooves.

Theoretically the same twist should be suitable for high and low velocities with a given projectile; but the determination of the appropriate twist must, to a large extent, be settled by experiment. In the British service, a twist of one in 30 cals. is adopted for guns, and a sharper twist varying from one in 15 to one in 25 cals. for howitzers. In the French service it is considered that with an angle of rifling[1] larger than about 7°, the projectile would be given too much spin-stability, and would find difficulty in adapting itself to the trajectory when it commences to fall.

In American field guns the rifling has approximately 8 grooves per in. of calibre and is about 0·02 in. deep. In Germany, on the other hand, the changes in rifling appear to have been in the direction of narrower grooves and wider lands while the number of these has been increased; the twist of rifling is uniform.

*Obturation.*—In the British service, ordnance are divided broadly into two classes: (1) breech-loading (B.L.) and (2) quick-firing (Q.F.). Originally the division was in accordance with the rate of fire; but developments in breech-mechanisms and mountings have been such that, generally speaking, a modern B.L. gun is capable of a rate of fire as high as that of a Q.F. gun of equal calibre; so that, though still used, the terms B.L. and Q.F. are applied to guns according to the obturation, *i.e.* means adopted for preventing escape of gas at the breech. With B.L. guns the obturation is effected by the de Bange system (*see* 20.206). With Q.F. guns the sealing is performed by a metallic cartridge-case.

The principal advantages of the Q.F. system are: (1) the charge being in a metal case "fixed" ammunition can be used, thus increasing the speed of loading; (2) the cartridge contains its own means of ignition, again tending to increase the speed of loading; (3) if one case fails to obturate correctly, subsequent rounds are not necessarily affected. On the other hand, the disadvantages are: (1) it is not suitable for guns of large calibre owing to the excessive weight and length of the cartridge-case required; (2) the chamber must be of a definite shape and size and must be very accurately machined; (3) some form of cartridge-case extractor is required.

The advantages of the de Bange system (pad obturation) is its simplicity, no preparation of the gun being required beyond the machining of the obturator-seating. Its disadvantages, apart from the slower rate of loading, are that (1) pads are liable to lose their shape unless constantly attended to, and are susceptible to changes in temperature, becoming soft in hot weather, and hard and inelastic in cold weather; (2) prolonged firing causes overheating, softening and inefficiency of the pad; (3) if a pad fails to seal completely on any one round, the result is damage to the pad and scoring of the obturator-seating, which will increase with every subsequent round unless immediate steps be taken to remedy the defect.

*Breech-Mechanisms.*—The essential features of the breech-closing arrangements are safety, efficiency and rapidity; and the breech-mechanism must be so arranged as to embody these features as well as, at the same time, convenience in handling, which must also be studied, to admit of the mechanism being operated with a minimum amount of effort. A point of importance, as regards safety when a breech-screw is used, is to ensure that there be sufficient effective bearing surface of the screw in bearing with the breech-bush to enable the screw-threads to withstand the pressure on firing. This point affects the length of the screw and consequently the length of the breech, the heaviest part of the gun. Rapidity of action and ease of operation are chiefly mechanical questions and do not affect the design of the gun as such to any appreciable extent.

As regards carriages for light and medium field equipments, the factors which require consideration as affecting mobility or lightness of draught are as follows:—

*Weight.*—The draught necessary varies directly as the weight and inversely as the wheel-diameter. Thus the weight must be a minimum consistent with strength.

*Wheels.*—The wheel-diameter should be as large as possible within practical limits, and the breadth of tire sufficient to prevent the wheel from sinking deeply into soft ground. When possible, similar wheels should be used on gun-carriage and limber to ensure interchangeability; but this is impracticable as a rule in the heavier-wheeled carriages, in which the limber-wheels support only a small proportion of the weight. The wheels must be designed for the load they have to support. In the British service the latest light field wheel is 4 ft. 3 in. in diameter; earlier equipments used wheels 4 ft. 8 in. or 5 ft. in diameter; the heavy field wheel is 5 ft. in diameter. Other wheels of both wood and steel, and of larger diameter, are used with heavier tractor-drawn equipment. The mean diameter of the axletree-arm should be a minimum consistent with strength in order to reduce friction.

*Wheel-Tracks.*—Generally, the wider the track, the larger the upsetting angle and the greater the lateral stability, but a wide track tends to increase the draught, permits of side-play of the pole, and adversely affects wheeling or reversing operations. Thus the track should be narrow, consistent with lateral stability. The track of the limber and carriage-wheels should be the same, so that the limber-wheels may make the tracks for the carriage-wheels which support the greater weight; this tends to lighten the draught.

*Limber and Coupling.*—The trail in travelling acts simply as a connector. It should be short for compactness, thus enabling the carriage to be reversed within a small space; and narrow towards the trail-eye, allowing a large angle of lock and thus ease of manœuvre. The coupling must, for travelling over rough country, permit of limited vertical and twisting movements of the limber with respect to the carriage, or *vice versa;* and it must preserve the balance of the pole. The coupling in general use is the trail-eye and limber-hook which allow of free play of one with respect to the other; sometimes the eye is swivelled to permit of a rocking movement which further increases the flexibility of connexion.

For ease of draught there should be a slight reduction in weight on the limber-wheels as compared with that on the carriage-wheels, the ideal proportions varying between 2 to 3 and 5 to 6. With light equipments the total load is not rendered excessive by carrying ammunition in the limber, and this gives a suitable distribution for travelling. With medium horse-drawn equipments, it is undesirable to add weight with ammunition, but by hauling back the breech of the gun to a travelling position upon the trail a suitable distribution is obtained without increasing the load. With tractor-drawn carriages particular distribution is not necessary.

*Balance of Pole.*—It is important to take the weight of the pole off the horses as much as possible, and the limber is designed with this object in view. With medium equipments, the balance must be preserved while the gun is transferred to the travelling position; this necessitates a special coupling, known as a limber-connector, which is flexible and also supports the weight centrally on the limber-axle. The load is pulled from and supported by the limber-axle, so that the variation produced when distributing the load will not disturb the balance of the pole.

Other necessary elements of a carriage design are brakes which serve the usual purposes in travelling, and travelling clamps which lock the portions of the superstructure to the travelling support in order to reduce play.

To permit of the necessary three movements of the gun in action, a superstructure must be built up on the basic structure of the carriage. For traverse a component, known as an intermediate carriage, is pivoted vertically to the basic structure, so that lateral movement can be obtained through traversing gear. With light and medium carriages the intermediate carriage is pivoted near the front of the trail, with others to the platform. The most notable exception is the case where cross-axle traverse is embodied in the design, when the intermediate carriage is dispensed with. The front of the trail is moved bodily along the axle by suitable gearing; the sides of the trail are extended upwards to support the cradle. This method has an advantage in that the direction of recoil is always coincident with the centre-line of the trail; but the necessary wheel and axle movements tend to render traversing difficult.

For elevation, the intermediate carriage must be designed to carry, pivoted on a horizontal axis, a cradle which, under the control of elevating gear, can give the required elevation to the gun; the cradle is carried by trunnions in plain or roller bearings at the top of the intermediate carriage.

For axial movement, the cradle must provide a support on which the gun can slide, but must prevent it from having twisting movement; it must also carry the recoil system. Thus the cradle and gun must have guides, and the gun also a lug for attachment to the recoil system.

The superstructure thus consists in an intermediate carriage, a cradle, a recoil system, and gears for traversing and elevating.

During action, complete immobility of the firing support is required; this means that the carriage must be secured against backward, forward, side and turning movements. In a typical light carriage, backward movement is prevented by the spade; forward movement by using the brakes in conjunction with the spade; the side movement by limiting the traverse. For turning movement the standard aimed at is that the wheels shall not lift during recoil, nor the trail during recuperation.

[1] The angle of rifling is the angle which the twisting groove makes with the direction of axis of the gun. It is given by $\frac{\pi}{x} = \tan. \theta$ when $x$ is the number of calibres in which a complete turn is made. Thus a uniform twist of one turn in 30 cals. means an angle about 6°.

*Conversion.*—An existing gun design does not as a rule lend itself very successfully to conversion to another pattern, though the expedient is sometimes, from force of circumstances, resorted to. It is seldom that the power of a gun—that is, its range and accuracy—can be improved by alteration; but by altering the breech-mechanism or adapting the gun to suit a new carriage it may be possible to augment its tactical, if not its ballistic, power. As examples of conversions which have been carried out in recent years in various countries may be cited: the conversion of field guns from B.L. pattern to Q.F. pattern in order to avoid the expense of complete rearmament; the conversion of old-model guns and howitzers by cutting down and boring out, during the World War; and the very frequent expedient of remounting the piece on a new type of carriage.

As the requirements demanded of a carriage in the field become more exacting, so the design becomes less simple, and any adaptation of an earlier design more difficult. At certain limits it becomes more economical to build a new design.

In recent years, changes in design have been more frequent and far-reaching than during many years previously. Consequently, formerly the question of obsoleteness of an equipment was one which did not have a very definite meaning. The task imposed on a gun in the past was neither so severe nor so definite as at the present time; and so the idea of what constitutes obsoleteness has only lately required to be expressed explicitly. It may be taken nowadays that an equipment is designed for a certain definite purpose, and that when it can no longer perform the duty required of it, it has become obsolete. Nevertheless, to apply this proposition as a test in any given case is much more difficult than to enunciate it. Thus, during the World War, so many new designs of carriages were built on quite new lines and embodying quite new ideas, that it might be said that all carriages of earlier date are now obsolete. But such a conclusion does not necessarily apply to all natures of carriages; for instance, though with light field carriages any spring-recuperator is obsolete, it does not follow that with a fixed mounting spring-recuperation is not efficient. It is difficult to draw any decided line or define obsoleteness to cover all classes of carriage and mounting. All that can be said is that a system or mechanism, formerly employed, which no longer satisfactorily and fully fulfils the ruling conditions of any class of carriage, may be considered as obsolete for that particular class.

Nevertheless, though a method or design may become obsolete, the question of stocks has an important bearing on whether the equipments of obsolete design may be discarded; and this final decision rests almost entirely on the capability of the equipment to give reasonable satisfaction in the ballistic requirements.

From all the above it will be seen how intimately the elements of a design react upon one another, and how in its final version the design becomes a compromise between conflicting requirements and limitations. The table below collects some of these requirements in the case of field carriages. Juxtaposed, they indicate the nature of the designer's problem without the need of further comment.

## (II.) Manufacture

*General Method of Building a Gun.*—In the general methods of building a British gun very little change has taken place in recent years. The gun is either built wholly of steel tubes shrunk together, known as the "all-steel" construction; or the inner tube is reinforced by winding on layers of steel wire and the whole encased in an outer jacket, known as the "wire-gun" construction. This latter construction is that now generally favoured and the number of layers of wire and the distance from breech towards muzzle covered with wire depend upon the particular class of gun.

The 60-pdr. gun may be taken as an example in the process of gun design. In the Mark I. gun there is an "A"-tube, lined with an inner "A"-tube extending from the seat of the obturator to the muzzle and secured longitudinally by means of corresponding shoulders and a breech-bush screwed into the "A"-tube at the rear; the breech-bush is prepared for the reception of the breech-screw; the layers of wire cover a portion—about one-half—of the "A"-tube, extending from the breech end; the jacket covers the wire and extends towards the muzzle along about one-half the unwired portion of the "A"-tube, and is secured longitudinally by corresponding shoulders; the breech-ring is fitted over the rear end of the "A"-tube and is screwed to the jacket; the breech-ring is prepared for the reception of the breech-mechanism and is provided on the upper side with lugs for the attachment of the hydraulic buffer and running-out springs of the carriage; longitudinal ribs on each side of the jacket form guides for the gun in the cradle.

In the next mark of 60-pdr. the "A"-tube was made thicker and the inner "A"-tube omitted; and this was also the case in the Mark II. which was introduced as a more powerful gun, being some 5 cals. longer than the Mark I. The last mark, however, has an inner "A"-tube extending from the seat of the obturator and slightly projecting from the muzzle; the interior of the "A"-tube is prepared with longitudinal grooves to prevent any turning movement of the inner "A"-tube when in position; a lug is provided on the under-side of the breech-ring for the attachment of the hydro-pneumatic buffer of the carriage; and projections on the under-side of the jacket are formed to fit the slides on the cradle.

The measurements of the chamber of the 60-pdr. are: largest diameter, 6 in.; smallest diameter, 5·3 in.; length 21·926 in.; and the total length of the latest pattern gun is 192·25 in.

Recently another method of building a gun, termed "auto-frettage," originating with the French, has been tried as an alternative to shrinkage, but it is still in an experimental stage.

The rule hitherto has been to limit the greatest strain developed in a gun-body to the value corresponding to the strain produced by a tensile stress equal to the elastic limit of the material. Beyond that limit permanent deformation takes place. But it is now argued that with any static load less than that which produced an existing permanent deformation, the total deformation will remain less than the maximum reached under the latter, and the permanent strain does not increase; so that a member statically stressed to a point quite beyond the natural elastic limit would be entirely safe under any static load extending below that point, and that the point may be considered as a new elastic limit and adopted as such for practical purposes. As applied to a hollow cylinder or a gun, auto-frettage consists in applying an interior pressure, preferably by hydraulic power, of such intensity as to cause deformation of the inner layers much beyond that corresponding to the natural elastic limit. The permissible interior deformation is based upon the ratio of outer and inner diameters, upon the physical qualities of the steel, and particularly upon the paramount condition of keeping the inner layers free from fissures and breaks. Precautions must also be taken so that, upon removal of pressure, the material of the inner fibres, which will then be under intense compression, will not be further deformed and weakened by these compressive stresses. In action—*i.e.* under interior pressure—all the layers are in a state of tension varying, of course, with the radial position of any given layer. On returning to rest, all the layers tend to return to original lengths, but because of the permanent deformation, intentionally produced,

| Element. | Travelling requirements. | Firing requirements. | Governing factors. |
|---|---|---|---|
| Weight | Small for mobility. | Large for stability. | Travelling. |
| Trail—length | Short for compactness when limbered up. | Large for stabiltiy. | Firing. |
| Trail—width | Narrow at end for angle of lock. | Wide on axle to reduce intensity of shock. | Firing. |
| Wheels—diameter | Large for mobility. | Small for stability. | Travelling. |
| Centre of gravity / Centre of height | Affected by diameter of wheels. | Low for stability, high for command of fire. | Stability and command of fire. |
| Axle—length | Long for lateral stability, short for other points. | Sufficient to give required traverse. | Travelling. |

the inner layer, for instance, would be set to a new length greater than the original and smaller than that developed in action; it is then compressed by the combined efforts of all the surrounding layers. The result is that the whole body of the solid hollow cylinder is in a state of compression greatest at the interior wall and least at the exterior wall. As a gun has a tube of thickness diminishing from chamber to muzzle in order to conform to the variation of the powder gases, it is not possible to employ a uniform auto-frettage pressure throughout the length of the tube. With auto-frettage, though the elastic strength may be raised, the point of rupture must remain the same. The advantages claimed lie principally in economy of time, labour and material.

*Big Bertha.*—The method of manufacture of the German long-range gun, "Big Bertha," might be cited as an example of special adaptation. The gun was constructed from worn-out 38-cm., 45-cal. naval guns, used merely for the sake of the forgings. The converted gun was built in two parts, a main section about 30 metres long and a forward part about 6 metres long. The old gun was bored out and a very heavy tube of 21 cm. inside diameter inserted. Some 13 metres projected beyond the end of the original gun and over this portion another hoop was shrunk and locked to the forward hoop of the old gun. The main portion was rifled with uniform twist; the forward section, attached by means of interrupted threads and heavy outside collars as flanges, was not rifled but of a diameter larger by the depth of the grooves. The reason for the extra smooth-bore section was probably to align the axis of the projectile more perfectly with the axis of the gun and so to reduce to a minimum any irregularity of the projectile as it left the muzzle. The inner tube was made of such a thickness that, when worn too far, it could be bored out, *in situ*, to a larger diameter and the gun again used with a larger projectile; and this operation could be carried out twice.

With the 60-pdr. gun the rifling in the Mark I. was of polygroove plain section of uniform twist, one turn in 30 cals., with 24 grooves. In the latest mark of gun the rifling is the same shape and twist, but there are 32 grooves.

Whereas, in England, formerly the method of cutting the rifling was to cut one groove at a time, the tendency now is to cut two or three grooves at a time, as it is found that sufficient accuracy can be maintained during the working; thereby time and cost are saved. But it is thought that to cut more than three grooves at once is dangerous to the required accuracy. In America the practice of cutting all the grooves at the same time is favoured in certain instances, and with the 75-mm. field gun the method of rifling the bore enables the whole 24 grooves to be worked upon at the same time.

*Recent Developments in Breech-Mechanisms.*—As regards breech-mechanisms, that known as the "pure couple" mechanism is practically the standard type for all heavy and most medium guns in the British service. Greater ease is ensured by its use, as the breech-screw is balanced by equal and opposite forces applied to the two studs on the breech-screw, thus eliminating any tendency to lateral translation of the screw, and so reducing wear and friction.

With the French "mortier de 293 mm.," automatic withdrawal of the breech-screw is effected by power stored up by the recoil of the piece. The screw is of the Welin class, and is prolonged to the rear by a tail-piece with steep threads fitting with an attachment from which an arm passes ending in a sleeve movable about an extension of the recuperator piston rod. This extension is fixed to a carrier between the arms of which lies the sleeve attachment from the breech; a toe-piece on the movable part engages with the recuperator body and can move in a cam-groove. As the gun recoils, the recuperator body, with the sleeve interior, moves with it; the carrier sliding along the cradle passes over a pawl. On recuperation the carrier is arrested by the pawl, and the arm between the breech-block and carrier is held while the gun continues to complete the run-up; on account of the screw-thread on the breech-block tail-piece, the screw is obliged to turn and is thus withdrawn from the gun. After loading, the pawl is put out of action and the pressure of the recuperator, by forward and turning motion combined, effects the breech-closing.

With the Schneider 105-mm. gun of 1913 pattern, the breech-mechanism has a special rapid movement. The screw is of the swinging type. Plain and thread segments alternate as usual, but the dividing lines between them, instead of being parallel to the axis of the gun, are drawn to a curve and the breech-block is hollowed on the side nearest the pivot. The carrier-ring is cranked and pivots on an axis somewhat displaced to one side. The combined effect of these arrangements is that the block can swing into and out of the breech-opening without a separate movement of translation. The necessary motion is imparted by a lever actuating a rack on the breech-face of the breech-block which rotates teeth on the breech-block; one-quarter turn locks or unlocks the breech. The extractor arm lies in front of the breech-block pivot and is operated by it through a cam system.

The breech-mechanism for light field guns has followed generally on the lines of those for heavier B.L. guns. The British 18-pdr. Mark I. equipment contained a novel feature, in that the breech-screw was coned throughout its whole length, the *larger* diameter being in front, so that when the breech was closed it had a wedge-action which precluded any possibility of the block being blown out.

Another form of breech-closure is the Canet system adopted in the French 240-mm. coast gun of 1903. In this a semicircular block prepared with screw-threads is pivoted transversely in the body of the gun. In the closed position the block is above its axis, and it is maintained there against gravity by special mechanism. On recoil, this mechanism disengages itself automatically, and the breech-block, no longer supported, swings down into the open position.

A recent type of breech-mechanism—known as the Asbury mechanism—has been introduced into the British service, being intended primarily for howitzers. The distinctive features of this are a vertical or fore-and-aft motion of the breech-mechanism in lever, an arrangement whereby increased mechanical power is gained at the final moment of closing the breech and at the first moment of opening it (thereby avoiding forcing and slamming); and a form of catch which prevents the breech-screw from revolving during the swinging motion of opening and closing. This type of mechanism has proved very satisfactory, and has been applied to howitzers of heavier natures, as well as to light and medium field guns. The advantages claimed for it are: (1) it facilitates the service of the gun by placing the breech-mechanism lever in a more convenient position; (2) it prevents slamming of the breech and eliminates damage to the threads of the breech-screw due to rebound of the mechanism; (3) it has a positive unseating action on the obturator.

With sliding wedge-mechanisms the two main types still remain the vertical or falling block and the horizontal sliding block. It is necessary with the sliding block that the guide ribs along which the block slides should be inclined so that the block, as it moves to the closed position, has also a forward movement, thus forcing the cartridge into its seating in the chamber of the gun. The method of operating the block, in the main, remains the same as in early designs, but additional mechanism has been introduced to enable the mechanism to be worked semi-automatically, particularly in connexion with firing at aircraft at high angles of elevation, when it is necessary to adopt some mechanical means to assist in loading, and to prevent the cartridge slipping back while the breech is being closed.

With the latest type of mechanism, the practice is to use separate locks for electric and percussion firing. These locks follow generally on the lines of the combined lock, but a much lighter mainspring is used in the electric lock; and the percussion lock is usually so arranged that it is automatically cocked during the opening of the breech. Guns and howitzers fitted with the Asbury type of mechanism were originally intended for firing with a vent-sealing friction tube, no lock being required; but this method proved unsatisfactory chiefly on account of the excessive erosion of the vent. As a temporary expedient, the Martini rifle-firing mechanism was adapted to the vents of these pieces, and fired a percussion tube similar to the small-arm cartridge. It has been superseded by a lock and slide-box.

With 18-pdr. field guns the striker is designed for percussion firing only, having a trip action in which the striker is cocked and released by a continuous pull on a lanyard or a firing lever on the carriage.

*Carriage Elements.*—The kinds of trails in use for mobile equipments may be classed as pole, box and split.

The pole trail is merely a steel tube and favours travelling rather than firing, being light, a simple connector, and permitting of a large angle of lock; its greatest defect is the limitation it imposes on the elevation of the gun.

The box trail consists of two bracket sides connected at either end; its main feature is to permit of increased elevation, as the gun can move down between the side brackets, and it is the standard type for use with modern 3-point-support carriages. This type, on the other hand, does not favour travelling so much as the pole trail, as it is heavier and is necessarily wider at the travelling front, thus diminishing the angle of lock. When used with an axle-traverse equipment the trail can be narrower, since it traverses with the gun.

The split trail consists in two similar legs attached at the front by ball and socket joints to the axletree, and a crossbar; the legs are splayed outwards for firing; the flexible connexion allows of a limited vertical movement to accommodate the legs on uneven ground. This construction is necessarily heavier and hence adversely affects the mobility; its great advantage is provision of an extended traverse. The first practical example of the split trail was the Deport Q.F.

field gun used in the Italian army. The principle is applied also in the British 3·7-in. mountain howitzer. No German guns used in the war had split trails. Perhaps the best-known split-trail weapon is the French 155-mm. G.P.F. gun used also by the Americans.

The *spade* is secured to a sole-plate and the latter to the under-side of the trail at the rear; the spade prevents rearward movement of the carriage while the sole-plate prevents the trail from sinking into the ground. Spades are generally broad and shallow, for a deep-pointed spade is likely to be damaged when bedding and may not give sufficient clearance for travelling. With axle-traverse equipments the spade must be more pointed, as the trail pivots about it, and it must also prevent lateral movement of the trail.

The spike is a special form of detachable spade, which requires to be driven through a slot in the trail; the point of the trail is in fact nailed to the ground. Spikes differ from spades mainly in that there is no limitation within reason to their depth; their removal facilitates travelling; they have to be driven in in taking recoil, whereas the ordinary spades bed themselves; they prevent forward movement during recuperation, and braking is unnecessary.

The axletree, which must be made to withstand the downward blow due to firing, may be either straight or cranked.

The straight axletree is usually a steel tube having the ends tapered to form arms to receive the wheels; straight axletrees must of necessity be used with axle-traverse equipments. The cranked axletree is favoured by the modern 3-point support carriage. It consists in a hollow steel forging, the extremities of which are cranked upwards, and to which are attached tapered arms for the wheels; the central or low portion supports the front of the trail. Cranked axles generally have to be made heavier than straight axles. Their great advantage is that they enable the firing height to be lowered and so increase both the travelling and firing stability. Thus, with a given wheel-diameter, a cranked axle admits of a shorter and lighter trail, and stability is maintained with a more compact carriage.

During firing, the function of a brake gear is to prevent forward movement of the carriage during recuperation if spades be used; with spikes brakes are not necessary. All brakes must be provided with a form of quick release for use when a new line of fire is to be taken up, and also, in the case of cross-axle traverse, when the traversing gear is operated.

The typical intermediate carriage consists in two bracket sides suitably connected; it is pivoted near the front to the trail, slides over the trail at the rear under the control of the traversing gear, and has trunnion bearings forward at the top. Holding-down clips are normally provided at front and rear to prevent lifting on firing; and stops to limit the traverse to the designed amount each way. With a split trail a different pattern is necessary owing to the splaying of the legs; it is therefore pivoted to the centre of the axle, the upper portion is forked and provided with trunnion bearings, while the lower portion in the form of a stem passes through the axle tree and fits into a ball-joint in the cross-bar beneath.

The traversing gear is generally of the nut-and-screw type; in the main it consists in a screw with hand-wheel supported in a bearing pivoted to the trail and engaging with a nut pivoted to the rear of the intermediate carriage. With split-trail carriages, the screw is supported by the intermediate carriage and engages with a nut pivoted to the left of the axle. With axle-traverse equipments, either the central portion of the axle is threaded to form the screw and the nut carried within the front of the trail or a separate screw and nut parallel to the axle are employed; in the latter case, rollers support the front of the trail on the axle, and ease in traverse is obtained by the incorporation of ball-bearings.

*Cradles* may be distinguished as of the ring and trough types. The ring cradle is in the form of a short hollow cylinder in which the gun is supported and through which it recoils; chambers are formed on top or below to accommodate the recoil system; and the cradle is pivoted transversely to the intermediate carriage by means of trunnions. This type is used principally with heavy howitzers and fixed mountings in which relatively short recoil-length is given. It is not a good design for long-recoil field guns because of its shortness, and relatively bulky construction. The trough cradle is shaped like a trough, trunnions being formed on either side to pivot it to the intermediate carriage; the recoil system is housed within the trough, while the gun is supported on slides above. The trough forms a suitable casing for the recoil system and is less bulky than the ring type and assists rearward extension; on the other hand, it tends to bend during firing and necessitates the carrying of the recoil system below the gun.

Elevation is given by means of a screw and arc, or arcs, which causes the cradle to pivot about the trunnions. The screw may be single or telescopic to give aggregate motion; its lower end passes through a nut supported by the intermediate carriage and operated through a bevel drive. Generally, with light equipments the gear is designed to embody the principle of the "independent line of sight." Any elevating gear should support the cradle either centrally or equally on either side so as to reduce torque and wear. The modern method is to employ either a central arc, or one on either side, operated through a worm-and-arc-pinion drive. Owing to the high elevation for which equipments are now designed, with light and medium natures an arrangement to facilitate quick loading is necessary to permit of the cradle being depressed by hand from a high elevation to a convenient position for loading without disturbing the elevating gear or sight; when this is embodied, the arcs are sleeved on the trunnions, while the arrangement provides the means for locking them to or unlocking them from the cradle; with heavier equipments quick and slow motion gears are installed.

Shields are provided for light horse-drawn equipments, and give protection against shrapnel and rifle bullets only. Such protection is not considered necessary with heavier equipments; and the weight of a shield to give protection against shell-fire would be prohibitive. The typical shield is supported on the axle and trail, and is provided with hinged flaps at top and bottom to give additional protection; these flaps are folded up for travelling.

Heavy mobile equipments which cannot be travelled as entities are split into loads—generally three—the gun, the cradle, and the firing platform. For the gun a special travelling carriage is provided; for the cradle and platform axle-arms are attached upon which wheels can be placed, and a light limber keyed to the load.

The latest pattern of 60-pdr. carriage embodies most of the modern ideas; it is a typical 3-point-support carriage, and its main features are: a travelling load of 6 tons drawn by 8 heavy-draught horses or by tractor as an alternative; wheels of 5 ft. diameter with 6-in. tires, and extension felloes fitted to increase the tread for travelling over soft ground; a 79-in. track to give a large upsetting angle and the necessary traverse; a distribution of the load in the approximate proportion of 5 to 3 on the carriage and limber wheels respectively, obtained by transferring the gun to a travelling position on the trail; a special limber connector to preserve the balance of the pole; a cranked axle to give greater lateral and firing stability; brake gear cross-connected and operated from either side; a box trail to permit of 35° of elevation; a wide trail for 4° of traverse each way; a long trail for stability; a shallow and broad spade; an intermediate carriage with holding-down clips; nut-and-screw traversing gear with spur drive and ball-thrust bearings; an extended trough cradle, mounted on roller-bearings, to support the centre of gravity of the recoiling parts even at full recoil; a single centrally placed elevating-arc operated by worm-and-arc-pinion gearing; hydro-pneumatic recuperator and controlled recoil; a recoil of 54 in. at the horizontal, reduced to 24 in. at 35° of elevation; replaceable bushed bearings for all working parts. (F. M. R.)

### (III.) Wear and Life of Guns

Erosion is a general term applied to the effects produced by the action of the powder gas on the bore of a gun. These effects are of two kinds: (1) the gradual enlargement of the bore and smooth wearing-away of the surface by the action of the gas behind the projectile; this is termed "wear," and is independent of the sealing of the bore by the projectile; (2) the irregular eating-away of the surface of the bore in holes and gutters; this is called "scoring," and is mainly due to imperfect sealing of the bore. These two actions may occur separately or conjointly, and with cordite charges the differences are marked.

In the latest high-velocity B.L. guns, in which the sealing is nearly perfect, wear occurs with very slight or no trace of scoring until towards the end of the life of a gun. When a new gun is taken into use with cordite charges, wear begins at once; the lands near the breech end of the bore are worn down rapidly, while the grooves are also worn, but not to the same extent as the lands. The wear is always more with cordite than with gunpowder and is much more rapid with Mark I. cordite than with M.D. cordite. The rate of enlargement increases greatly with the weight of charge and pressure, and a heavy gun wears much more quickly than a light gun; for example a 9·2-in. can fire only about 600 rounds with full charges, whereas an 18-pdr. Q.F. gun can fire 10,000 or more rounds during its life. The "wear" per round is greater at first than subsequently.[1]

[1] The following figures as to the "life" of German land service ordnance during the war have been published (Schwarte, *Militärische Lehren des grossen Krieges*):—

| | Average | In some cases |
|---|---|---|
| 7·7-cm. field gun | 15,000 | 20,000 |
| 10·5-cm. field howitzer | 10,000 | 13,000 |
| 10·5-cm. gun | 10,000 | 15,000 |
| 13·0-cm. gun | 3,500 | 6,000 |
| 15·0-cm. heavy land howitzer | 15,000 | 20,000 |
| 15·0-cm. gun, model 1916 Ehrhardt | 2,200 | 3,000 |

The table makes no distinction between the 96 n.A. and the 16 patterns of field gun, nor between the various patterns of 10·5-cm. field howitzer and gun.

"Scoring," once it begins, increases very rapidly and grows at an increasing rate as firing progresses. A tool-mark in the vicinity of the seat of the projectile is likely to start scoring; but its importance is lessened the further it is from that point. Scoring is chiefly found on the front incline of the chamber, and thence for a few feet down the bore. So long as it continues to increase only gradually in proportion to the number of rounds fired it may be considered normal and of no great consequence while it remains within certain limits.

In addition to the eventual unserviceability of the gun, the effect of wear and scoring is shown during the life of the gun by a gradual falling-off of muzzle-velocity and accuracy.

During the World War, in which ammunition expenditure far exceeded what was foreseen, several new expedients were used to augment the life of the guns. To this requirement is largely due the lengthening of howitzers, the increased use of reduced charges, and the development of new projectile forms which in comparison with the old gave equal results with and smaller strain on the gun, or brought a given target within the range of a smaller (and longer-lived) gun.

Apart from these indirect methods, various expedients were applied to the gun itself, notably by the French. For instance, in the 145 new heavy field gun provision was made in the design for boring out to 155 mm. after a first life at the normal calibre, and the 155 G.P.F. when worn had its chamber lengthened, the rearmost 12 in. of rifling being removed. (X.)

### (IV.) Buffer and Recuperation Design

On firing the recoiling gun acquires kinetic energy which must be absorbed by a resistance acting over the recoil permitted; this resistance is provided by the buffer, recuperator and friction. To reduce the recoil velocity and energy, particularly with field carriages, the heavier portion of the recoil system is generally made to recoil with the gun, the lighter portion being fixed to the cradle. The recuperator returns the gun to the firing position after it has come to rest under the action of the recoil resistance. It must be designed with a reserve of power, and so it assists in checking recoil.[1] The buffer must absorb the energy not accounted for by the recuperator and friction, and must adjust the total resistance as required by the carriage. With field carriages stability must be kept during its action.

The buffer consists of a cylinder filled with oil in which works a piston and rod; either the cylinder or, more usually, the rod is fixed, the remaining portion recoiling with the gun. A flow-space for the liquid, arranged to decrease during recoil, is provided between the piston and cylinder. The hydraulic resistance of the liquid to being forced through the flow-space causes pressure on the face of the piston and a pull on the rod. The greater the flow-space the less is the pull on the rod, so that by a suitable arrangement the resistance can be varied.

Modern buffers are tension buffers, the piston-rod being withdrawn during recoil. A compression buffer, in which the rod is pushed in, has the disadvantage that the free space in the cylinder cannot be fully occupied by liquid, as room must be kept for the volume of the rod when it enters. One compression buffer, however, is in use, in which the rod is extended beyond the piston and passes out of the cylinders through packing, thus permitting the cylinder to be completely filled.

At full recoil, a length of the piston-rod is withdrawn leaving a partial vacuum; on recuperation the liquid must be banked up against the face of the piston remote from the rod before the buffer resistance can take effect. At this instant the gun has its maximum recuperative velocity, and the larger the ratio of diameter of piston to rod the sooner will the buffer resistance act as a control. The flow-space in the buffer increases during recuperation, and the resistance is not sufficient to absorb the surplus energy. A further controlling device is therefore provided to ensure that the gun comes quietly to rest in the firing position.

The stability of a field carriage increases with the elevation, and at the horizontal it demands that $R \times H$ must be less than $W \times L - w_r \times X$.

Further, not only must the carriage be steady, but it must have a definite stability-margin throughout recoil; thus, if N represents the percentage increase in R to reach the stability limit—

$$\left(1+\frac{N}{100}\right) R \times H = W \times L - w_r \times X$$

or

$$R = \frac{100}{100+N} \cdot \frac{W \times L - w_r \times X}{H}$$

throughout recoil. The stability-margin of N per cent should be at least 25, and in modern carriages approximates to 50.

*Methods of Control.*—From these conditions it is seen that the resistance to recoil must decrease uniformly with recoil, and hence the system of graduated resistance is employed with field carriages. While the gas is acting on the gun, the recoil should be as unrestricted as possible, in order to preserve the aim of the gun and to reduce the couple on the recoiling parts. Frequently the maximum buffer resistance does not come into action until the gun has moved from 10 to 15% of the total length of recoil. A typical resistance-space diagram for graduated recoil is shown in fig. 2.

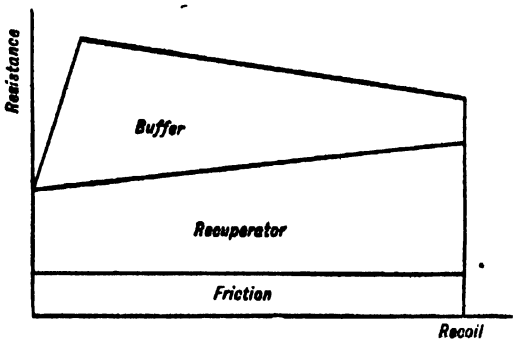

Fig. 2.—Resistance-space diagram. Graduated recoil.

The condition to determine the length of recoil is that the maximum recoil energy with free recoil (which can be calculated from the ballistics of the gun) must be equal to the work done by the total resistance to recoil, that is, to the area of the resistance-space diagram. Thus the working length of recoil, which for a light field carriage varies from 40 to 45 in., can be determined; and the buffer resistance can be obtained from the diagram, for the recuperative and frictional resistance can be calculated with reasonable accuracy.

The system of "controlled" resistance—shortening the recoil as elevation increases—is employed with many modern field guns and howitzers on account of firing at high elevations, as there is not space to permit of the same length of recoil as at the horizontal. Since stability increases with the elevation, it is possible to increase the buffer resistance with the elevation and thus shorten the recoil. A typical resistance-space diagram for this system is shown in fig. 3. Comparing fig. 3 with fig. 2 it can be seen how the proportion of energy absorbed by the buffer increases greatly with the elevation.

With a fixed mounting the question of stability does not arise. Consequently the recoil is fixed at from 3 to 4 cals. depending on the working stress on the mounting. As the recoil must not be exceeded at the greatest elevation, the component of the recoiling weight must be allowed for. The design must be such as to absorb the energy at the greatest elevation. Further, the total resistance will be a minimum when maintained constant throughout recoil. "Equalized" resistance to recoil is adopted with fixed mountings. A typical resistance-space diagram for this is shown in fig. 4.

*Buffer Dimensions.*—The buffer dimensions depend on the following considerations. The length of the buffer must allow of a metal-to-metal recoil slightly greater than the working length determined.

[1] In certain modern equipments the energy stored in the recuperator during recoil is used not only to run the gun up but also to actuate the mechanism which unlocks the breech-mechanism of the gun, holds it back while the gun runs forward, and then, after reloading is completed, brings the breech-block up to and into the breech opening and locks it. A French example is given above. (C. F. A.)

The diameter of the piston-rod must withstand, with a safety margin, the tensile and compressive stresses to which it is subjected. The rod must be capable of being effectively packed and easily handled in manufacture. With light equipments the diameter as calculated is usually too small for effective packing, for which about 1 in. is the minimum diameter; with heavier equipments the calculated diameter increases and is used in the design.

The diameter of the cylinder is determined, within limits, by the design of the carriage. The larger the cylinder, the less the pressure required to act on the face of the piston and the sooner will the control of recuperation become operative; but a large cylinder has to be

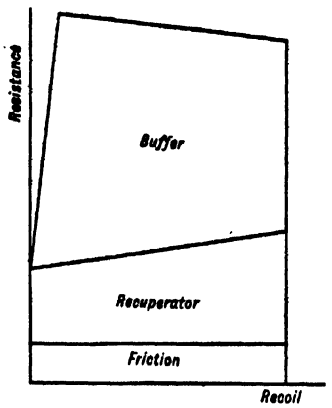

FIG. 3.—Resistance-space diagram. Controlled recoil.

made proportionately stronger, and therefore heavier to withstand the bursting stress to which it is subjected. The ratio of the diameters of cylinder and rod usually adopted is about 2 to 1. The necessary thickness of the cylinder is then determined from the pressure it must stand.

The ratio of the areas of the piston and rod is 4 to 1; consequently the control to recuperation becomes operative at ¼ of the total run-up. This must be in accordance with the stability requirements, and the sooner it becomes operative the greater stability-margin will be preserved. With some equipments the ratio is less, so that the control becomes operative at a slightly later stage; but the ratio should be such as to give a stability-margin.

*Flow-Space.*—The area of flow-space can be calculated from a knowledge of the resistance-space curve, the velocity-space curve during recoil, and the piston area; the calculated area requires to be corrected experimentally.

Typical velocity-space and flow-space curves are shown in fig. 5.

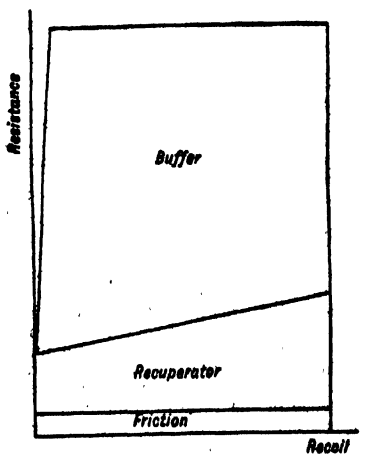

FIG. 4.—Resistance-space diagram. Equalized recoil.

The experimental correction of the flow-space is carried out in two ways: (i.) by taking practically a velocity-space curve for the recoil and altering the apertures until this curve corresponds with that obtained theoretically; (ii.) by taking a pressure-space curve by means of an instrument known as the buffer-gauge. To obtain good pressure curves the maximum flow-space should correspond with the maximum velocity of recoil.

The modern methods of varying the flow-space are as follows:—

(*a*) A circular piston and longitudinal grooves, usually of constant width and varying depth, cut internally in the cylinder. The piston tends to become fluted with wear, for which no ready means of compensation exist. Some pre-war field carriages use this system.

(*b*) Rectangular slots or ports in the piston, sliding over one or two longitudinal valve-keys,—metal bars of such contour as to leave the required flow-space during recoil—fixed to the cylinder walls. This system is simple, but, owing to the difficulties of accurately cutting the valve-keys, it is suitable for only relatively short recoils.

(*c*) A hollow piston-rod with circular piston sliding over a tapered rod, holes being cut in the piston-rod near the piston for the passage of the liquid. This system is more suitable for short than long recoils owing to the difficulty in accurately tapering a long rod; with it control to recuperation becomes operative from the first instant. It is used with the systems of equalized and graduated resistance.

(*d*) A rotary piston, with two or more ports cut in it, fitting loosely on the rod, rotation being governed by ribs fitting into grooves in the cylinder, and a valve with corresponding ports, against which the piston rotates, fixed to the piston-rod. This method is used with modern field carriages with combined systems of graduated and controlled resistance to recoil; it is the method of variation which best lends itself to controlled recoil. It has advantages, in that a slight turn of the piston-rod regulates the flow-space, and that wear of the piston or valve can be compensated for in a smaller manner.

(*e*) A modification of (*d*), in which grooves form the flow-space, is found in the latest German equipments. This consists in a hollow piston and rod with an extension tube carrying intermediate and stop rings; corresponding ports are cut radially in the piston, intermediate ring, and extension tube, while ribs on the intermediate and stop rings engage respectively with straight and rifled grooves in the cylinder. When elevating, the piston and tube are rotated to reduce the flow-space, eventually cutting off the intermediate ports; the variation in flow-space is obtained by the rifled grooves passing gradually off the ports.

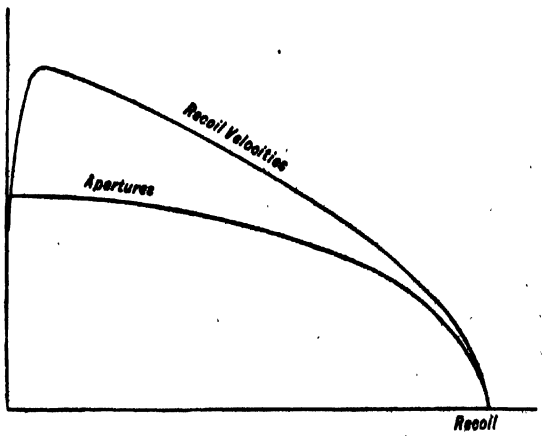

FIG. 5.—Typical velocity-space and flow-space curves.

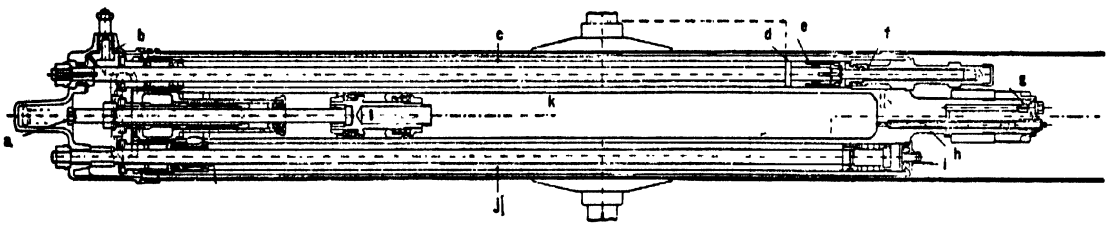
Controlled recoil necessitates cut-off gear to rotate the piston-rod automatically with the elevation. This gear consists in link or cam-gearing placed between the cradle and the intermediate carriage, and rotates the rod through a bevel drive as the cradle is elevated. This rotation causes an overlap of the piston and valve ports as the piston is held stationary by the grooves, thus reducing the flow-space, so that the cut-off may take place earlier in the recoil stroke.

*Control of Recuperation.*—As the buffer flow-space is greatest at the termination of recuperation, some check is required to prevent a metal-to-metal blow. To produce this final control, the main devices in use are:—

(*a*) The control plunger and chamber. The plunger may be an extension of the piston-rod and the chamber a recess in the cylinder into which it fits; or the plunger may be fixed to the cylinder and the chamber a recess in the piston-rod. The flow-space is formed by cutting a tapered flat on the plunger, and in modern designs the construction provides for a further adjustable exit for the liquid so that the control may be regulated according as the elevation is low, medium or high. The recess becomes filled with liquid during recoil, and, before the gun can run up and the plunger return to the recess, the liquid must be forced through a small flow-space by the entry of the plunger. With this device recuperation takes place in three stages—first, unresisted except for friction, secondly, resisted by the buffer and friction; thirdly, resisted by the buffer, control plunger and friction.

(*b*) Separate recoil and running-up valves as used with the rotary piston buffer. The recoil and running-up valves which are on opposite sides of the piston are permitted slight longitudinal movement but prevented from rotating on the rod; the running-up valve is pressed against the piston during recuperation and a clearance obtained between the piston and recoil valve which renders the latter inoperative. The rotation of the piston decreases the flow-space

between it and the running-up valve and provides the necessary control. Recuperation takes place in two stages: first, unresisted except by friction, and, secondly, resisted by the running-up valve of the buffer and friction. This method was largely used in America.



(*c*) A rod working inside a hollow piston-rod used with the tapered rod buffer. The end of the tapered rod is fitted with a slide-valve which permits liquid to pass over it and fill the piston-rod during recoil; on recuperation the valve closes, and before the tapered rod can enter the piston-rod it must displace the liquid over the valve and through a groove, or grooves, of decreasing depth cut internally in the piston-rod. As the piston-rod is designed to fill during recoil, the control becomes operative from the commencement of recuperation.

(*d*) A modification of (*c*) is the principal German method. The piston-rod is designed to fill during recoil, the liquid having to pass out through a shallowing groove cut in a cylindrical control rod. A spring-loaded valve, which permits the piston-rod to fill during recoil, has its periphery shaped further to regulate control.

*General Arrangement.*—With field equipments, the buffer and recuperator cylinders are bored in a steel ingot which is supported in a trough cradle and is lugged to and recoils with the gun; the piston-rods are secured to the cradle cap (fig. 6). The main features secured to the cradle. On recoil, the system works telescopically, the total deflection, equal to the recoil, being divided between the two banks; it has the advantage that the deflection per column is reduced, and stiffer springs of shorter free length can be used.

An air recuperator consists in a quantity of air under compression in a container and in contact, either directly or through liquid, with a movable piston. On recoil relative movement is given to the piston and container and the air further compressed. The air subsequently reacts on the piston and recuperates the gun. The difficulty of sealing compressed air accounts principally for the use of liquid with field-carriage recuperators, for the liquid seals the air and is itself sealed by packings. Thus air-recuperators may be classed as pneumatic, in use with field carriages; and hydro-pneumatic, in use with fixed mountings. Hydro-pneumatic recuperators may be further subdivided according as the liquid is in direct contact with the air, or is separated from it by a floating piston.

With hydro-pneumatic recuperators one cylinder contains liquid which acts on the face of a packed piston connected by its piston-rod to the cap of the cradle, and communicates through a throttling valve, port and pipe with the other cylinder containing liquid and compressed air; the throttling valve permits a free passage for the liquid during recoil, but closes to control the rate of recuperation at

FIG. 6.—General arrangement of buffer and recuperator.

of this type are a rotary piston for variation of flow-space, a control chamber with an adjustable liquid exit to provide recuperative control according to the elevation, a tank for reserve oil supply, a cut-off gear for controlled recoil, and a valve to release any air that may be sucked into the cylinder during recoil. The cylinder at the point where the piston-rod enters is closed by a stuffing-box, soft packing, and gland.

With fixed mountings the buffer cylinder is secured to the underside of a ring cradle, the piston-rod being lugged to the gun. The features are a valve-key, a control-plunger protruding inwards from the closed end of the cylinder and working inside a hollow in the piston-rod, and a tank for oil supply. The open end is closed by a self-tightening ring of L-section, stuffing-box, packing and gland.

*Recuperation.*—Recuperation may be by means of steel springs or compressed air. Whichever the method, the recuperator must possess sufficient initial pressure to return the gun to, and hold it in, the firing position at the greatest elevation.

The life of springs is limited; according to the calibre and weight of gun with which they are used so their weight increases and they suffer from fatigue. In single columns they are unsuitable for long-recoil guns, due to the large deflection necessary. The springs used are cylindrical spiral springs of round or rectangular-section wire; wire of flat rectangular section permits of greater deflection before the spring is crushed metal to metal and hence is that usually employed; but circular-section wire gives a spring of minimum weight. To obtain the best results, the length of initial compression should be equal to the deflection produced by recoil.

Spring design consists in determining, consistent with the limitations of the carriage, the section of the wire, the mean radius of the coils, the number of coils, the free length, and the initially compressed length of the spring; this can be done from known formulae, and as a spring when compressed is subjected almost to pure torsion the deflection is proportional to the load producing it.

Spring systems may be either single or telescopic columns; in Great Britain the former arrangement is used with short-recoil and the latter with long-recoil guns.

A typical single column is mounted on a compressor rod with end plate secured to the gun, and is carried in a spring-box secured to the cradle; it is subdivided into springs, placed end to end and separated from one another by parting plates. On recoil, the rod is withdrawn from the spring-box, between which and the end plate the springs are compressed; subsequently the springs extend and recuperate the gun.

In the telescopic system, the springs are divided into inner and outer banks and arranged to surround the buffer-cylinder which recoils with the gun; they are subdivided for convenience. The two banks are separated by a concentric tube, flanged to connect with the inner bank at the rear and with the outer bank at the front; the buffer-cylinder is flanged to bear against the inner bank at the front, whilst the outer bank bears at the rear against the casing the commencement of run-up; the outlet of the pipe is designed to be below the liquid level at all elevations and depressions to prevent air from passing into the lower cylinder.

It is necessary that the correct quantity of liquid be in the system, so that the designed ratio of compression and terminal pressure of the air may not be disturbed. The initial air-pressure varies from 500 to 700 lb. per sq. in. according to the equipment.

A disadvantage with those systems in which the air is in direct contact with the liquid is aeration (*i.e.* frothing or churning). Thus in a later type the upper cylinder is fitted with a packed floating piston to separate the air from the liquid to prevent aeration. The floating piston has a tail-rod projecting into the cradle-cap, which has the effect of increasing the pressure on the oil in front above the air-pressure in rear so that there is no tendency for air to leak past the piston; whilst the position of the tail-rod—visible from outside—acts as a simple tell-tale to indicate correct filling, and consequently any leakage of liquid. Leakage may be replaced by a screw-actuated force-pump until the tail-rod is correctly positioned.

The working length of the recuperator is the length of recoil, and the total initial pressure required is determined as previously indicated. The diameter of the piston-rod is obtainable from the maximum stress it has to withstand, but must not be less than 1 in. for convenience of packing.

The ratio of compression of the air—*i.e.* the initially compressed volume divided by the finally compressed volume—should be low, to reduce the terminal pressure and heating effect; little is gained by exceeding 2, and it is best taken between 1·5 and 2.

The larger the area of piston head, the less the initial pressure required, and it is desirable to keep this low for convenience in sealing and charging; but, relatively to the air-cylinder, the piston area must be small to give a low ratio of compression. Consideration of piston packings leads to the decision that they must be capable of withstanding a steady pressure up to the maximum initial pressure and a momentary pressure as high as the maximum terminal pressure.

From a knowledge of the ratio of compression, the piston area, and the length of recoil, an estimate of the volume of the initially compressed air can be arrived at; this decides relatively the sectional area of the air-cylinder, and the initial pressure when a floating piston with tail-rod is used.

The whole design, as regards bulk, is limited by the constructive arrangement of the cradle; but the desiderata are a low initial pressure and a low rate of compression, both of which entail bulky construction, more particularly of the air-cylinder. With field equipments the initial pressure is generally higher than with fixed mountings owing to the greater limitation imposed as regards bulk.

*General Remarks.*—The advantages of air recuperators when compared with springs are, first, that an increase in power can be readily obtained without increasing materially the weight of the equipment; secondly, the recuperator in addition to the buffer acts to control run-up; thirdly, the troubles consequent on springs break-

ing or taking a permanent set are obviated. On the other hand, air recuperators require the services of a skilled artificer for their maintenance, and as they absorb relatively a greater proportion of the recoil energy than springs a loss of pressure is likely to overload the buffer much more than a spring breakdown; the correct charging of the system is, therefore, absolutely necessary.

The air used in recuperators must be dry and free from dust to prevent rust and abrasion; at high temperatures, moist air is the cause of pitting. An inert gas—nitrogen—is used by the French, and tends to preserve the "mirror" surface necessary with the cylinders. The liquid used in buffers and recuperators is usually a mixture of certain percentages of neat's foot and hydro-carbon oils, and must have certain qualities, namely, non-freezing in any climate; freedom from acid for preservation of packings, cylinders and working parts; a slight viscosity not greatly affected by considerable changes in temperature; non-inflammable. The buffer flow-space is designed for a specific liquid of certain viscosity, and therefore only that specified should be used. In emergency, however, glycerine will serve.

*Packing.*—Packings may be distinguished as joint-rings, soft packings, and self-tightening rings. Joint-rings—copper, leather or vulcanized fibre—are used with plugs, stuffing-boxes, etc. Soft packings, composed of asbestos, lead and hemp, and moulded to shape, are used in stuffing-boxes to retain liquid at normal pressures and to centre the piston-rod. Self-tightening rings, of leather or hydraulic rubber, U- or L-section, are employed to seal liquid under pressure. Frequently a combination of soft packings and self-tightening rings is used; the shock pressures are resisted by self-tightening rings whilst the soft packings prevent leakage when travelling or at rest.

*Differential Recoil.*—This system, which dispenses with a buffer for absorbing recoil energy, has been tried by the French and Germans. In the first round the gun is hauled back against the recuperator by pinion and rack-gearing to the extreme recoil position, retained by a catch, loaded and laid; on releasing the catch, the gun is driven forward by the recuperator and fired by a catch when nearing the forward position. Thus a forward movement is in progress at the moment of firing, and acts against and diminishes the recoil energy; when firing is in progress the gun is driven back by the recoil at each round. If a miss-fire occurs, the carriage would be liable to upset against the front; to obviate this, forward buffers are provided to stop the gun.

*Recoil Absorbers* attached to the muzzle, by which the muzzle blast is utilized to force the gun forward and thus diminish the resultant backward force producing recoil, were tried in 1921.

*Combined Buffer and Recuperator.*—The system of a separate buffer and recuperator is that which normally obtains; the only known exception in which they are combined and dispense effectively with a buffer is the French 75-mm. field equipment.

The recuperator—in principle a hydro-pneumatic recuperator of the floating-piston type—also acts as the recoil brake, for which purpose the air-pressure must be high, about 1,200 lb. per square inch. A guide-rod of the floating piston passes centrally through a hollow rod with pistons at either end; one is equal in size and adjacent to the floating piston, whilst the other is smaller, to work in a chamber having graduated grooves to vary the flow-space—in effect, a control-plunger and chamber.

The energy of recoil is absorbed by the recuperator and by the throttling of the liquid in passing through one-way valves. On recuperation, the one-way valves close and the forward movement of the floating piston forces liquid over the small piston through the graduated grooves, whence it reaches the other cylinder and reacts on the recuperator piston; the control is provided by the decreasing flow-space due to the graduated grooves. Thus the system consists in a recuperator combined with a buffer to control the run-up only.

The energy of recoil is utilized for hydraulic power in the 9·2-in. fixed mounting. Hydraulic cylinders, called compressors, are fixed to the cradle, and in them work rams which recoil with the gun. The compressors are connected with a spring accumulator by pipes filled with liquid. On firing, the liquid in the compressors is forced through the pipes and a non-return valve into the accumulator; a relief valve fitted to the accumulator acts when the latter is fully charged, the liquid then passing through the valve to a tank. On recuperation, a vacuum tends to form in the compressors, so that liquid is sucked into them from the tank through a valve and pipe in preparation for the next round. The accumulator is connected by pipes with two hydraulic hoist cylinders, the pressure to which is controlled by valves operated by levers; and the liquid in the hoists returns through an exhaust-pipe back to the tank when the rams descend.

(F. M. R.)

### (V.) Types of Ordnance

At the beginning of the World War, the first matter that engaged the technical branches of the artillery of the fighting nations was the mobilization of all available guns. Old siege, fortress, naval and coast-defence pieces, and even modern pieces not immediately required in their existing situations, were mounted on improvised field carriages or railway mountings and sent to the front. The vast increase in the production of ammunition that soon became necessary was at first an administrative rather than a technical question. As the war progressed, new material and new designs were required to meet the exigencies that arose. The development of artillery material during and after the war came under two principal headings:—(*a*) simplification in design of existing equipments and ammunition to admit of mass production; (*b*) design and production of new equipments to meet the altered conditions of warfare.

A gun equipment of 1914 was a highly specialized engineering product. The cost of the gun was small relatively to that of the personnel of the army, and it was possible to spend time, labour and money on producing an ideal machine in which every ounce of weight should serve a useful purpose. Expensive materials such as high-grade steel and bronze were freely used without regard to any possible difficulty in procuring them during a long war, and complicated designs such as that of the bronze cradle of the British 18-pdr. were adopted without considering the difficulties of mass production.

In every country, when vast quantities of guns and ammunition had to be made, and when non-military factories had to be turned into arsenals, the first task of the technical branches of the artillery was to simplify and standardize designs. Common steel, of stouter section, was used in place of high-grade steel; cast iron replaced brass where possible, and rigid limitations of weight were relaxed. The general result was a relatively simple and almost clumsy design, easy to manufacture, highly finished in essential parts only, and capable of rough usage.

The alterations in the design of existing guns, other than those intended to facilitate manufacture, were mostly directed towards obtaining longer range, the main reason for this being the increase in depth of a system of defences from a single trench line to a series of defensive zones several miles deep. The Germans met the situation boldly, in spite of their manufacturing difficulties, by the issue of a new long barrel for their field-gun equipment, and an upper carriage which enabled elevation up to 40° to be given. Similarly they lengthened the light field howitzer, the 4-in. medium gun, and the 6-in. gun. Their heavier natures did not lend themselves to conversion, and new equipments had to be designed. However, streamline shell (*see* Ammunition) were issued which enabled longer ranges to be obtained. The French bent the trail of their field gun to allow a few degrees more elevation. They had only 105 field howitzers, so these had to be manufactured. They met the shortage of long-range howitzers by using old guns bored out to 8-in. cal. and mounted on high-angle carriages as howitzers. The British improved the carriage of the 18-pdr. field gun and issued a new 6-in. howitzer. The British army had no heavy guns or howitzers except those mounted for coast defence, and the heavy guns for the war were at first taken from the navy.

*New Equipments made during the War.*—Speaking generally, these were neither novel nor original. There was no time to test new ideas, and artillery authorities fell back on old and approved designs, modified in the direction of greater power (at the expense of lightness) and simplicity of manufacture. Even the British 18-pdr. Mark IV. field gun, which looked very different from its predecessor, was only a reversion to established Continental practice. The German "75-mile" gun was not a new design, though it came as a surprise to laymen and even to most artillerists. Before the war, artillery scientists had advocated a new system of differential recoil, known in different countries as the *dynamic cradle*, the *canon lancé*, and the *Vorlaufgeschütz*. In this system a Q.F. gun was fired while in rapid forward motion under the impulse of the recuperator, thus reducing its recoil-energy so that a much lighter carriage could be used. Although a French mountain gun of this type already existed, this new system was not even tried in any of the equipments brought out during the war, and complications such as the automatic and semi-automatic breech-mechanisms gave place to simplicity and "fool-proof" gear.

*Post-War Equipments.*—All the nations which took part in the war have now a complete armament of guns, and some of

there is likely to being out a new equipment, except on a small scale, for some years to come. Experimental models, to meet the anticipated requirements of the future, are being designed. The ruling considerations are:—

(*a*) Railway mountings for all mobile heavy guns, motor transport for all medium guns, and, in a few years' time, for field guns as well. This allows of a considerable increase of weight and power, but a field gun must still be light enough to manhandle and small enough to conceal.

(*b*) Heavy flat-trajectory guns will be superseded to a great extent by heavy howitzers, throwing a shell to the same distance with less effort, and consequently less wear of the bore.

(*c*) The range of field guns and of howitzers will be materially increased, partly by the introduction of high-angle gun-carriages (such as the split-trail carriage described below), partly by lengthening the barrel, and partly by the use of streamline shell for long-range fire.

(*d*) All artillery will be designed principally for use from the covered position, and will have all-round panorama sights for the purpose of indirect laying.

(*e*) All high-velocity guns, even field guns, will use reduced charges as well as full charges, in order to avoid excessive wear of the bore. They will also use "super-charges" when extra long range is required. Practically, therefore, every gun will require three sets of sighting graduations, and three range tables, like a howitzer. This will probably imply either separate or separable ammunition. Powder must be flashless as well as smokeless.

(*f*) Calibres will be as few as possible, and ammunition, component parts, sights, and fittings will be standardized wherever practicable to facilitate supply.

(*g*) Equipments will be designed with a view to mass production under war conditions.

(*h*) Shrapnel shell will be used only in field guns, field howitzers, and mountain guns, on account of the difficulty of manufacturing shrapnel shell and time fuzes on a war scale. Practically all land service pieces will fire H.E. shell with percussion fuzes, and special projectiles such as gas shell (if their use is admitted), smoke shell, and incendiary shell.

All new equipments have panorama sights. In the graduation of these sights, degrees and minutes are being superseded by "mils," the mil being the angle subtended by 1/1000 of the range. Since all guns will have to fire two charges, and in most cases three charges, the range-drums will require several sets of graduations, masked so that only the set in use is visible. The French have set the example of deciding that all sights in the service are to be uniform as regards the method of setting, so that a layer from a field battery will be able to lay a 14-in. gun without special instruction. This is necessary in view of the constant interchange of personnel in time of war.

*Artillery Motors.*—Artillery of all calibres up to, and even including, 8-in. guns is now moved by road and across country by motor transport. The Austrians even moved 16·5-in. howitzers by road, as will be seen. But it is considered that in future all guns over 8 in. will be transported by rail. Although horse draught is still maintained for field artillery, at any rate in part, the post-war field guns are being designed to weigh 32 cwt. in action, which is some 10 cwt. more than was considered permissible in a gun which had to be drawn across country by horses at a trot. That is to say, they are designed primarily for motor transport. Artillery motors are described here only from the technical artillery point of view.

*Motor Tractors.*—The old-fashioned steam traction engine with its 8-ft. wheels was used at the beginning of the war for slow road draught, notably in the transport of the heavy German howitzers to Antwerp. This was practically incapable of moving anywhere off the road. A more generally useful type was the F.W.D. (four-wheel drive) petrol tractor, with each wheel separately driven. This was capable of moving over easy ground, but could not cross obstacles. This type is by no means extinct; and a good specimen of it is the small Pavesi tractor. The Austrians used a 100-H.P. Daimler F.W.D. tractor, and they afterwards used 8-wheeled carriers with every wheel driven by electricity generated by a 150-H.P. petrol engine and dynamo on a separate vehicle. The French used the ordinary petrol-driven motor lorry for the rapid transport of field guns for long distances by road. In some instances the gun was carried on the lorry, but latterly the men and ammunition were carried on the lorry, and the gun was limbered up to it. As the gun-carriage, on ordinary artillery wheels, soon broke up when drawn at a fast pace over paved roads, they fitted special wheels with thick rubber tires. No success has yet been attained in fitting road springs to a gun-carriage, as these will not stand the strain of firing and travelling across country. The Russians, however, in their 1903 equipment, fitted india-rubber block springs to their limbers and ammunition wagons. The method of drawing guns behind motor lorries was used by the French for reinforcing troops in the fighting line, and the divisional artillery limbers and teams were used to transport the guns from the road to their positions. The principal artillery transport motor used during the war was the caterpillar tractor, with two linked steel belts called "tracks"—bearing on the road instead of wheels. These were mostly of the Holt pattern. They were efficient tractors, both on the road and across country, but they were subject to the disadvantage that they cut up the road surface badly; if all artillery vehicles were of this pattern, the roads would soon become impassable.

The 2½-ton Holt tractor used for the American field guns during the war was 9 ft. 6 in. long and 4 ft. 10 in. wide, the extreme height being 6 feet. It was driven by an 8-cylinder motor giving 70 H.P. at 2,500 revolutions, and traversed 15 m. an hour on a good road.

In Italy, the lack of draught horses suitable for artillery has caused the authorities to take the lead in converting the field artillery, both of the divisions and the reserve army formations, to motor artillery. The divisional artillery is to be drawn by agricultural tractors; that at present favoured is the Pavesi tractor. This is shown in fig. 7, but the military pattern has smooth wheels with "grousers" which can be attached for cross-country work. The tractor has a 4-wheel drive, and weighs 2·35 tons only. The motor gives 25 H.P.; the road speed is 4 m. an hour and the cross-country speed about 2 miles. This is a much less powerful machine than the American 70-H.P. 2½-ton tractor, but it is intended to draw a gun weighing only 20 cwt. against 32 cwt. for the new American gun.

The reserve army field artillery will be drawn by fast motor lorries, and the present proposal is to carry the gun on a low travelling platform with road springs, rubber-tired wheels, and a spring draw-bar. This platform is to be drawn by a road lorry, which can on emergency draw two such platforms. On the battlefield the divisional artillery tractors will convey the army batteries from the road to their positions in action.

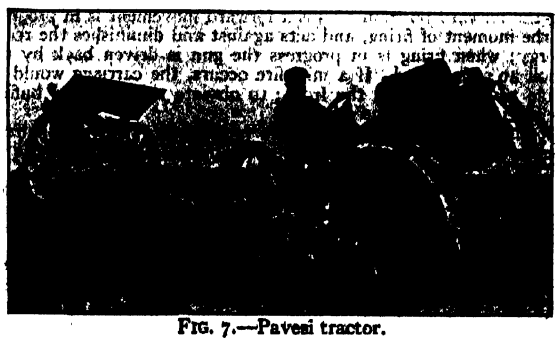

FIG. 7.—Pavesi tractor.

A problem now being studied in all countries is that of producing a caterpillar tractor or carrier that shall be able to work across country and shall travel on the road without injuring the surface. The most probable solution lies in the production of smooth-faced, preferably india-rubber-faced, caterpillar tracks which shall have sufficient adhesion not to slip on wet ground. The United States is now trying smooth-centred bands made of steel scales curved so that only the centre bears upon the road. The sides of the scales are cockled or indented so as to form a gripping surface; in soft ground the centre sinks in and the sides take hold of the ground and prevent the track from slipping.

Another possible means of combining a road carriage and cross-country carriage is to fit the caterpillar with road wheels. It is possible to extend the axles of the drums which drive the caterpillar tracks, and to mount road wheels on these extensions outside the tracks. The mechanical difficulties could be overcome, but this solution is not viewed with favour by motor designers. The resulting vehicle would be cumbrous. Thus the Schneider automobile mounting for the 220-mm. gun is 9 ft. wide; if fitted with road wheels the width would be 11 ft. 6 in., and even with the wheels removed the projection of the axletree arms would be such as to render it impossible for another vehicle to pass it on a narrow road. If the road wheels were fitted in front of the vehicle and behind if instead of outside the caterpillar tracks, they could not well be motor-driven, and the whole vehicle would have to be towed by another motor. Power-driven road wheels inside the caterpillar tracks are possible but entail considerable complication in the mechanism, and would be too close together for stability.

Some of the French caterpillar vehicles were fitted with railway wheels inside the tracks, so that they could be drawn along the railway to a point near their destination. This was not a satisfactory solution as the vehicles were not strong enough to be included in a train. Conversely, the 240-mm. railway-truck mounting was fitted with lorry wheels to enable the truck to be conveyed by road.

The Austrian motor carriers for heavy guns, driven by electricity from a separate power vehicle, had railway wheels as well as road

wheels. The latter were fixed to the railway wheels when the vehicle left the railway for the road. The power vehicle also had railway wheels, and, with the carrier, formed a small independent railway train. The carrier could be included in an ordinary train if desired, but not the power vehicle which, in that case, had to be loaded on a truck.

The American Christie motor overcomes the difficulty of combining a road vehicle with a cross-country vehicle in another way. This motor has rubber-tired road wheels, four on each side. It can travel on the road at a fast pace on these wheels, or rather on the fore and hind wheels, the centre pairs being raised clear of the ground. To cross country a caterpillar track is put on round the four wheels on each side, the centre pairs of wheels being lowered to take their share of the weight. To put on the tracks, one-half of each track is laid out on the ground and the vehicle run on to them; the top halves of the tracks, which hang from the framework, are dropped on to the wheels and the ends pinned together so that the tracks are continuous. It is stated that this takes 15 min., and it is expected that the time will be reduced to 10 min. by improvements in the gear.

*Motor Carriers.*—A tractor is usually expected to carry the gun-detachment and a "first supply" of ammunition, besides pulling the gun. But the platform carrier is a separate type, performing the duties of an ordinary lorry, and also capable of carrying heavy weights across country. When a carrier is used for transporting a gun it is fitted with a ramp to enable the gun to be run up on to the platform and run down when it has to come into action. Some carriers have power winches for hauling the gun up. Light guns can, on emergency, be fired from the platform in a fore-and-aft direction, but not across it, since a modern field gun measures 10 ft. 6 in. from the lowest point of the wheels to the spade. The advantages of the carrier over the tractor are that the gun is not damaged by fast travelling on the road, and that in very deep boggy ground it is sometimes possible to carry a gun on caterpillar tracks, but impossible to drag it on its wheels. The principal disadvantage of the carrier is that the gun takes up so much space on the platform that there is no room for the men and the ammunition, and an additional vehicle is required to carry them. The tractor is therefore generally preferred to the carrier, as being a more economical form of transport.

The British tried a caterpillar platform-carrier fitted to take a 60-pdr. or 6-in. howitzer. It weighed 35 tons with the gun and 24 tons empty. It was too heavy to cross bridges, and was discarded as an artillery vehicle; it was afterwards used to carry up stores over the crater-field on the Somme.

The largest road carriers used were the Austrian 8-wheel-drive howitzer wagons, driven by electricity from a separate carriage. These are described below. They weighed 35 tons loaded, which is the limit of weight even for bridges on the great "national" roads. This method of propulsion reduces the weight of the carrier, as the engine is transferred to a separate vehicle; the Austrian carriers weighed 15 tons and carried 20 tons. Since, however, they are quite incapable of moving across country, the caterpillar type of carrier is now preferred to them, especially as this type also can be lightened by driving by electricity from an accompanying power vehicle.

*The Automobile Gun-carriage.*—This is quite distinct from the tractor and the carrier. It is a motor vehicle of the caterpillar type with the upper gun-carriage built into it, so that the gun and vehicle are inseparable. Several of these mountings, both of the ordinary and Christie pattern, are described with the guns for which they are designed. They admit of elevation up to about 40° being given to the gun, but not of traversing it; the gun is layed for direction by turning the whole mounting by means of the caterpillar tracks. In the heavier mountings, a small auxiliary motor is fitted for this purpose. A special pattern is the St. Chamond automobile gun-carriage described below, which has an electric drive, the power being supplied by a motor and dynamo in a trailer which follows the gun.

The automobile gun-carriage is mechanically efficient and the objections to it are tactical rather than technical. It is too big; it is conspicuous and difficult to conceal; it offers too large a target; and it requires an immense amount of labour and material to make a covered emplacement for it. While the gun is in action the expensive and vulnerable motor is exposed to fire, whereas it would be much better employed behind the line bringing up ammunition. On this account most artillerists prefer the tractor to the automobile carriage. Moreover, as regards field artillery, the administrative point of view decides the matter. No nation can afford to keep up in peace-time the number of military motors required for the field artillery of a national army; it must depend on civilian motors. And of these the only ones capable of moving across country are the agricultural tractors. These are the machines that will have to be developed so as to suit both civil and military requirements, and they are essentially different from the special type built for an automobile gun-carriage.

*Armoured Motors.*—Automobile gun-carriages can be fitted with ordinary bullet-proof shields, but they cannot well be armoured so as to resist direct hits from artillery. A field gun of pre-war pattern, at a range of about 3,000 yd., will pierce a 1-in. armour plate with ordinary shell, or a 2-in. plate with armour-piercing shell. A modern high-velocity field gun, firing armour-piercing shell, will pierce about 3 in. of armour at the same range. But a 3-in. plate weighs 1,160 lb. per sq. yd. If the automobile carriage were armoured in front only, it would require some 8 sq. yd. of armour, weighing over 4 tons, and would then be proof only against field guns firing from the front at ranges greater than 3,000 yd.

*Transport of Artillery Motors.*—The present types of artillery caterpillar tractors, carriers and automobile carriages are not suited to long journeys by road. The vibration caused by the ribbed steel tracks shakes them to pieces. Future motors will no doubt be better built, with spring-centred rollers and probably with smooth tracks. But all motors should be designed so that they can be transported by rail for long journeys. The practical limit of weight is the 40-ton commercial truck used on European railways; the limitations of height and breadth comply with the local loading gauge.

For road transport the extreme width ought not to exceed 8 ft., but some of the automobile mountings are 9 ft. wide. The principal limitation is that of weight, and is generally taken at 25 tons for main roads and 20 tons for by-roads, though many country bridges will carry only 15 tons. On the other hand, the bridges on the great main roads of the continent of Europe are mostly equal to 35 tons; much depends on the length of the wheel-base or the width of the caterpillar tracks. Practically, a 15-ton tractor was the largest size commonly used in the war, though the Germans used some 20-ton F.W.D. Daimler tractors, and the Austrians used 8-wheeled carriers up to a gross weight of 35 tons.

All road motors are liable to be stopped by the destruction of bridges, though it is anticipated that military motors will in future be built so that they can cross fords, and some will even be made to float. These are described under BRIDGING, MILITARY.

*Field-Gun and Howitzer Equipments.*—The British 18-pdr. (*see* 20.221), owing to its heavy shell, proved to be admirably suited to trench-warfare conditions, and remained the standard British field gun throughout the war. It underwent several improvements. In 1915 the spring-case was filled with oil, so that the running-up springs worked in an oil-bath; this reduced the vibration in running up and made the carriage steadier. In 1916 the springs were replaced by an air recuperator fitted into the old spring-case; this change was made on account of the number of springs crushed during rapid fire and the difficulty of replacing them. In 1918 a new barrel was issued, which had an improved Welin screw breech-mechanism, with the actuating lever pivoted horizontally instead of vertically, so as to work with a downward instead of a lateral pull.

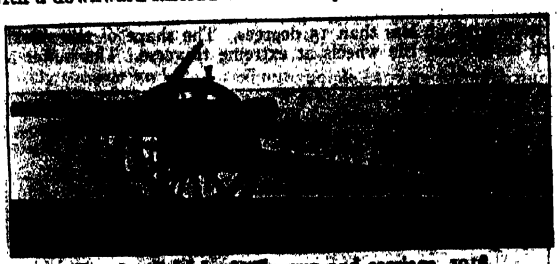

FIG. 8.—British 18-pdr. gun and carriage, 1918.

The carriage issued with this gun (fig. 8) is a modification of the normal type, with a trough cradle under the gun in place of the ring cradle which was a characteristic feature of the original 18-pdr. equipment. The lateral guide-rails on the old gun had always been a source of trouble, as the unsymmetrical section of the gun caused it to bend after continued firing. In the 1918 gun these are done away with and replaced by guide blocks which slide on the cradle. The cradle is extended to the rear [illegible] to give good support when the gun is in the recoil position. It contains the hydraulic buffer of ordinary variable-recoil construction and the pneumatic running-up gear now called the "recuperator." The lower carriage has a box trail instead of the old [illegible] with an opening in it which allows the breech to be depressed to give 30° (later patterns, 37°) of elevation, thus obtaining a range of 9,000 yd. with ordinary shell or nearly 11,000 yd. with streamline shell.

The carriage traverses on the axle as in the French equipments. The shield is fixed to the axle, and there is a small inner shield fixed to the cradle which closes the port in the main shield in which the gun traverses. The upper part of the shield is made to fold over. The weight of the whole equipment is not materially greater than that of the previous model, and the gun in action weighs 26 cwt.

Only one 18-pdr. battery of the above pattern was actually used in the war. The equipment did well, but the latest developments in field-artillery design, which are discussed below, made it undesirable to continue the production of this type, and a new gun and carriage, adapted either to horse or motor transport, was designed in 1919–1.

The French field gun is the 75-mm. (2·95-in.) Q.F. gun, well known as the *soixante-quinze* (fig. 9). It fires a 16-lb. shrapnel with M.V. 1,740 f.s., and an 11·68-lb. H.E. shell, M.V.

2,050 f.s. It did remarkably well in the war, and the only alteration made was to bend the trail so as to give room for 5° more of elevation beyond the 12° for which the carriage was built. The simple *collimateur* sight was replaced by a panorama telescope for all-round laying from the covered position. The gun was originally fitted with an arrangement which necessitated raising the trail shoulder-high on coming into action to allow the brake-blocks to fall under the wheels and then lowering it ("*abatage*"), but a modification which rendered this unnecessary had been brought out in 1914.

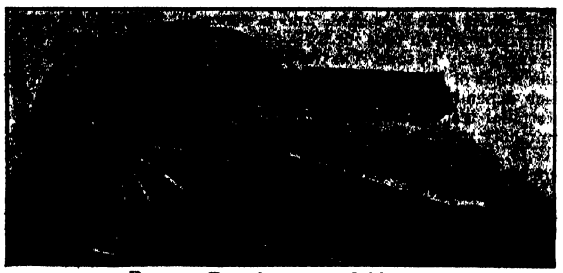

FIG. 9.—French 75-mm. field gun.

A new French field gun was in 1921 under trial. This fires streamline shell with super-charge at long ranges, and ordinary shrapnel and H.E. shell at medium ranges. A reduced charge is also provided, partly to save unnecessary wear of the gun and partly because, during the war, the flat trajectory of the French gun caused trouble when the artillery had to fire over the heads of the infantry. The 1921 gun is fitted both for horse draught and for traction by cross-country agricultural machines.

A very interesting modern equipment is the Schneider field gun shown in fig. 10. This was designed in 1918 to comply with the requirements of the French Government, but was not brought out till after the war. It is a 16-pdr. firing a streamline shell with M.V. of 2,000 f.s. and ranging 13,200 yd. at 40° elevation. It marks a new departure in axle-traversing equipments in that the carriage affords a traverse of no less than 15 degrees. The shape of the shield is such as to clear the wheels at extreme traverse. The buffer and

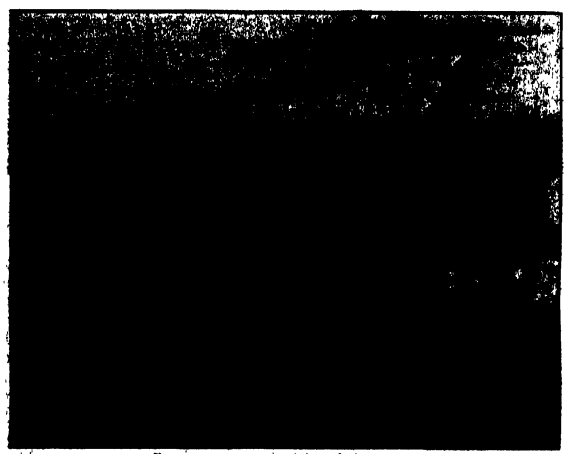

FIG. 10.—Schneider field gun.

recuperator are of the well-known Schneider pattern, but compressed nitrogen is normally used instead of compressed air as being less liable to corrode the recuperator reservoir. The cradle extended to the rear is a pattern which has come into favour since field-gun carriages have been required to give high angles of elevation. Its weight partly balances the gun and allows it to be set farther forward so that it has more room to recoil without striking the ground. Moreover, the open trough cradle is constructionally simple and suited for mass production in time of war. The cradle alone is not heavy enough to balance the forward preponderance, and balance springs are used enclosed in cylinders, one on each side of the cradle; one of these is visible in the illustration. The wheels, 4 ft. 7 in. in diameter, have stout solid-rubber tires, and it is claimed that the gun can be drawn over paved roads behind a motor lorry at 8 m. an hour without injury. The weight in action is 30 cwt., against 22½ cwt. for the French service field gun. This illustrates the modern tendency to increase the weights of field artillery in view of the introduction of motor traction.

Although this gun is a great improvement on any field gun used in the war, it would be unwise to accept it as the last word in field artillery. For instance, it is doubtful whether the traverse of 15° would nowadays be accepted as sufficient for firing from a gun-pit or for engaging tanks. For these purposes the split-trail equipment invented by the French Col. Deport (one of the designers of the original *soixante-quinze*) would appear to be the most suitable.

The Italian Deport split-trail field gun was issued in 1912 (see fig. 11). The gun itself is not remarkable; it was designed to take the same ammunition and give the same ballistics as the Krupp field gun already in the Italian service. It is a 14·3-pdr., M.V. 1,670 f.s., with a semi-automatic breech action. The peculiarity lies in the carriage. The trail is divided longitudinally, and each half is attached by a vertical hinge to the axle bed so that on coming into action the two halves can be opened out laterally at an angle of 60° to each other. Instead of the ordinary spade, there is a stout spike at each of the two trail ends which can be driven down by a hammer, so that the trail ends are nailed to the ground. The cradle with the gun is pivoted on the axle bed and can be traversed 30° right or left. In ordinary field equipments, in which the upper carriage traverses on a pivot, the gun traverses only some 2½° right or left; if it were traversed much out of line with the spade, the carriage would overturn sideways on firing. Axle-traversing gives somewhat more traverse, but even this is inadequate for modern tactical needs. In the split-trail equipment the carriage is perfectly steady so long as the line of recoil is between the two halves of the trail.

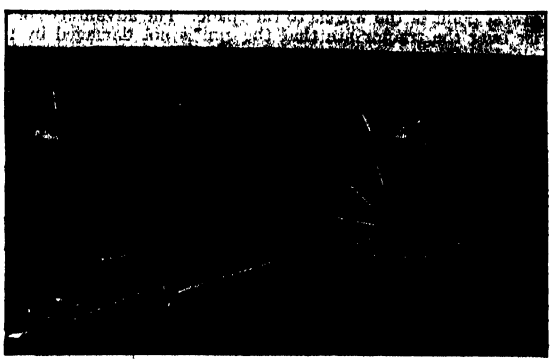

FIG. 11.—Deport field gun.

This enlarged lateral field of fire is of great value in modern warfare. In the first place, the gun may have to command a considerable arc of fire from a cramped gun-pit, and, to do so, an ordinary field gun must be traversed on its wheels. Being usually out of sight of the enemy it is layed by a distant mark in flank or rear or by aiming-posts. For accurate shooting the gun must be traversed without shifting it laterally; any displacement of the gun would mean a considerable error in direction. Under these conditions the split-trail carriage is of great advantage, since it offers a fixed pivot about which the gun can be traversed without moving the trail or wheels. In the second place, a field gun must now be capable of hitting a moving tank, and this, especially at short range, implies rapid traversing through a wide arc. A split-trail gun can keep up rapid fire on a tank crossing its front, while the fire of an ordinary gun would be checked and delayed by the necessity of constantly lifting the spade and swinging round the trail.

A further peculiarity of the Deport gun is the high angle of elevation obtainable with the split trail, since there is nothing in the way of the recoil. The Italian gun can be elevated to 50° to the horizontal. The inventor introduced this feature for the purpose of firing at aircraft, which in those days were expected to fly within 3,000 ft. of the ground. Even so, a low-velocity gun with curved trajectory such as the Italian field gun would not have been of much use. But the increased elevation has proved valuable as a means of obtaining the long range which is now required of a field gun.

The Deport field gun has double recoil gear. That is to say, the gun is not mounted directly on the cradle containing the main recoil gear, but on a pedestal sliding on the main cradle, which has a small buffer and recuperator of its own. This arrangement has the advantage of keeping the recoil gear cool, since the hot gun is at some distance from the main buffer and the heating due to the friction of the liquid in the buffer is divided between two buffer-cylinders. Otherwise this duplication of the recoil gear constitutes an undesirable complication, especially with regard to considerations of mass production in war-time. The gun and carriage proved quite serviceable during the war; no alterations were made in them, and in spite of the somewhat low power of the gun the equipment was retained in the service afterwards.

The Schneider split-trail field gun of 1914 is a great improvement on the Italian gun, since it fires a streamline shell of 16 lb. with M.V.

1,700 f.s., and ranges over 10,000 yd., while the weight in action is only 19½ cwt.

The Russian field gun was considered by many artillerists to be an injudicious combination of ballistic elements, as its 14½-lb. shrapnel was too light for its very high M.V. of 1,930 f.s. However, it was a fairly efficient shrapnel gun and did well in the first campaigns of the war, till trouble in the Russian factories and the destruction of Putiloff arsenal by fire reduced the output of ammunition and entirely stopped that of shrapnel and time fuzes.

*The American Post-war Field Gun.*—The United States' pre-war field gun was an early pattern of quick-firer by Ehrhardt of Düsseldorf. In 1916 a split-trail equipment was designed, but the American

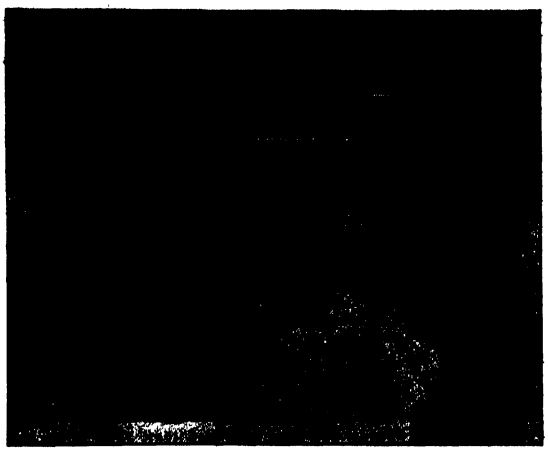

FIG. 12.—American field gun, 1920.

artillery used the French 75-mm. gun during the war. An American 75-mm. equipment is under trial (1921), the specification for which was originally as follows:—Range 15,000 yd. with 15-lb. H.E. shell; split-trail carriage to give 30° traverse and 80° elevation; M.V. 2,175 f.s.; variable controlled recoil; smokeless and flashless powder; weight in action, not more than 32 cwt. The gun has been made and approved; it gives ballistics slightly in excess of those required. The carriage was made, but was found rather too heavy. The split-trail carriage had been intended for a "universal" field carriage to take either the field gun or the field howitzer, and to give 80° of elevation with the latter; this made it heavier than it need have been to take the gun only. A box trail carriage was therefore brought out; this gives only 10° traverse and 45° elevation, but is well within the limits of weight.

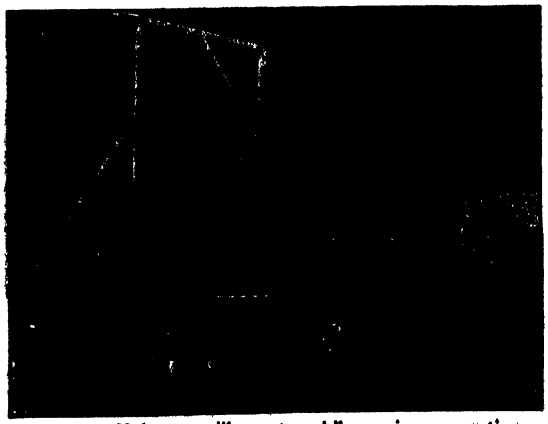

FIG. 13.—Holt caterpillar automobile carriage, mounting 105-mm. howitzer, 1920.

The gun on box trail carriage is shown in fig. 12. It is known as the 75-mm. gun, model 1920. The gun is said to weigh only 7·37 cwt., which is remarkably light for its power. It is 42 cals. long, has a horizontal sliding-block breech action, and has constant recoil (42 in.). It fires a 15-lb. H.E. shell ranging 15,100 yd. with super-charge, which gives a M.V. of 2,175 f.s. With the ordinary charge the M.V. is 1,500 f.s., this low velocity being purposely adopted to save the wear of the gun. The shrapnel is heavier than the H.E. shell, weighing 17 lb., and should be a very efficient projectile with the super-charge, with which its M.V. is about 2,040 f.s. With the ordinary charge the velocity would probably be too low and the trajectory too curved for good bullet-effect. Both the shrapnel and the H.E. shell have a forward centring band. The shrapnel has a clockwork fuze made by the Waltham Watch Co., and the H.E. shell is of the thick-walled class with base percussion fuze.

The cradle trunnions are set far back, giving a forward preponderance which is supported by a balance-spring called in America an "equilibrator." This feature is met with in almost all carriages giving high angles of elevation. The carriage traverses on the axle 5° each way. The wheels are only 4 ft. in diam., as against 4 ft. 8 in. in the pre-war equipment; this reduction is necessary to keep the carriage steady in firing without the use of a very long and heavy trail. Solid-rubber tires 3½ in. in diam. are fitted, to enable the gun to be drawn at a fast pace behind a motor without injury.

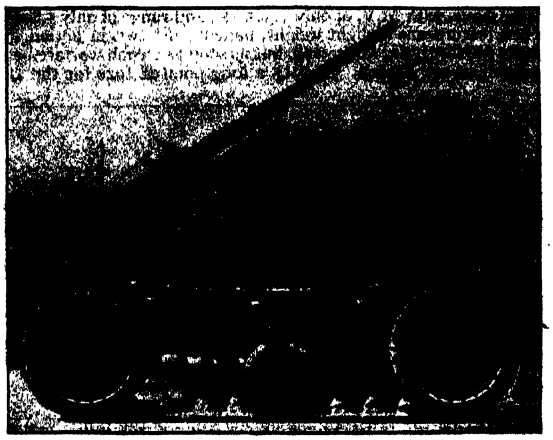

FIG. 14.—Christie automobile carriage.

The main shield of the American field gun is fixed to the trail and traverses with the gun; there is a folding top-shield and a hanging shield under the trail. The gun has the independent line of sight and is sighted with the panorama sight. The Americans graduate their sights in "mils," a mil being the angle subtended by 1/1000 of the range, which is about 3·6 minutes. This method, first introduced by the Swiss, afterwards adopted by the French, and now employed by the artillery of almost all nations, is a great improvement on the cumbrous system of degrees and minutes.

During the war an improvised automobile carriage for field guns was made by mounting the gun on a 5-ton Holt caterpillar tractor. This mounting allows of 45° elevation and 28° traverse; it weighs 6 tons complete. The power is the same as that of the 2½-ton tractor, and the highest road speed is 9 m. an hour.

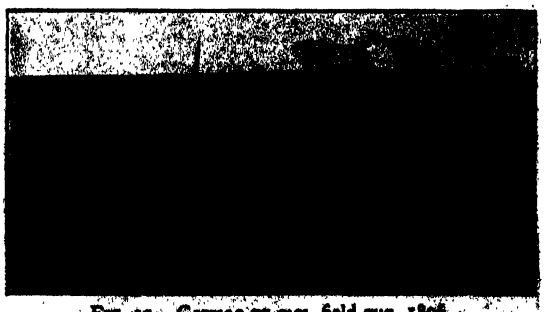

FIG. 15.—German 77-mm. field gun, 1896.

This was followed by the 1921 Holt caterpillar automobile carriage for field gun and field howitzer shown in fig. 13. It is capable of 30 m. an hour on the road—an unprecedented speed for a caterpillar as these machines, as hitherto built, are subject to violent vibration and consequent damage when run at speeds beyond a walking pace. In this case the entire mounting is spring-supported, the drums carrying the caterpillar tracks are rubber-cored and rubber-covered, and rubber is used on the track shoes, track rollers, front idlers, and drive sprockets. The tracks are as light as possible, even the connecting-pins being hollow. The main frame is supported on coil-springs in rear and a plate-spring in front; the latter acts as an equalizer between the two front track drums, so that one track can rise 15 in. higher than the other. Removable shields are carried.

The field gun lies along the top of the carriage when travelling. For firing it is elevated on the cradle trunnions, which are set well to the rear, the resulting forward preponderance being balanced by springs. It is probable that the new pneumatic balance springs will be used, as described below for the 6-in. carriage. Owing to the position of the trunnions, the gun recoils down the rear of the mount-

ing, not between the frames, and it is therefore necessary to use outriggers projecting to the rear, with spades which are bedded in the ground before firing. At low elevations the gun can be fired without using the outriggers. The illustration (fig. 13) shows the carriage with the 105-mm. howitzer at the moment of recoil. The photograph taken with $^1/_{25}$ sec. exposure, indicates by its sharpness the steadiness of the carriage.

The 1921 Christie automobile carriage for the U.S.A. field gun and howitzer is shown in fig. 14. It is of the type described under *Artillery Motors*, travelling on wheels when on the road and as a caterpillar across country. In other respects it is similar to the Holt 1921 automobile carriage.

*German Field Guns.*—The 77-mm. field gun "96 n.A." (fig. 15) was a 15-pdr. with M.V. of only 1,525 f.s., and range of only 5,800 yd. Its best feature was its light weight, namely, 18½ cwt. in action, and in open warfare it did fairly well, but as soon as trench warfare began it proved nearly useless. In 1915 a long pointed fuze for the H.E.

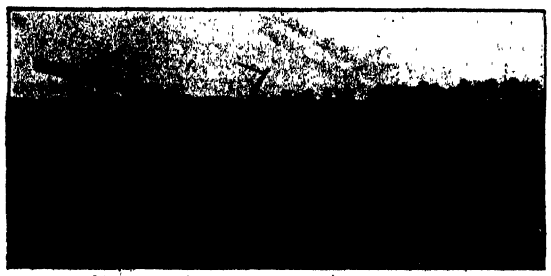

FIG. 16.—German 77-mm. field gun, 1916.

shell increased the range by about 700 yd. As the range was still insufficient, in 1916 they issued a new field gun (fig. 16). The calibre was the same as before, but the gun was lengthened from 27·3 to 35 cals., and an upper carriage was added which allowed the gun to be elevated up to 40 degrees. This enabled a range of 11,700 yd. to be attained with a streamline shell weighing 13 lb., M.V. 2,007 f.s. As this shell had two driving-bands, the new gun had to be rifled with uniform twist. Three charges were used: a reduced charge, an ordinary charge for the 16-lb. shell, and a super-charge for the streamline shell. Owing to the use of the three charges, the fixed ammunition was replaced by separate ammunition. During the open warfare of 1918 the long field gun, which weighed 27·5 cwt. in action, was found too heavy, and was partially withdrawn in favour of the old shorter and lighter "96 n.A."

The field guns used by the other nations engaged in the war were of no special interest; all were light 15-pdr. of moderate power, and all except the Austrian gun were ordinary Krupps or Schneiders.

FIG. 17.—British 4·5-in. field howitzer.

*Field Howitzers.*—A field howitzer is a piece equal in mobility to the field gun, capable of throwing a shell of 30 to 40 lb. It was formerly expected to attain the same range as the field gun, namely about 6,000 yd.; but now that field guns fire at 45° elevation and range 15,000 yd. it is obvious that field howitzers of equal mobility cannot throw their heavy shell to the same distance. The pre-war field howitzer had already attained its limit of range, except for such increment as could afterwards be attained by the use of streamline shell, and if the post-war field howitzer is to range farther it will have to be heavier than before. It already has been seen that in some of the new field-gun equipments, intended primarily for motor traction, the weight in action has been increased to 30 and even 32 cwt.; and with a slight increase on the latter weight it is now possible to build a howitzer throwing a 33-lb. shell 12,000 yd.

The British 4·5-in. field howitzer was designed by the Coventry Ordnance Works and was considered to be the best weapon of its class used in the war, though it will no doubt be superseded in course of time by a weapon of longer range. It fired a 35-lb. shell and ranged 7,200 yd.; the weight in action was 24 cwt. The recoil was controlled by rotating valves in the piston of the hydraulic buffer and was shortened at high elevations to prevent the breech from striking the ground. The howitzer was originally designed to fire shrapnel only and gave excellent results. During the war the issue of shrapnel was discontinued owing to difficulty of supply. Thereafter the howitzer fired H.E. shell with sensitive fuzes and proved a most valuable weapon for cutting belts of barbed wire.

The French had no field-howitzer equipment in 1914 and during the war they relied mainly on howitzers of the 155-mm. class for high-angle fire. A certain number of Schneider 4·2-in. howitzers were, however, used. This fired a 35-lb. shell, ranging 6,000 yd. It was of simple construction, with constant long recoil and a long cradle extended to the rear as in the 1918 Schneider gun. It weighed only 22½ cwt. in action. The new French field howitzer will be heavier with a split-trail carriage and range about 11,000 yd.

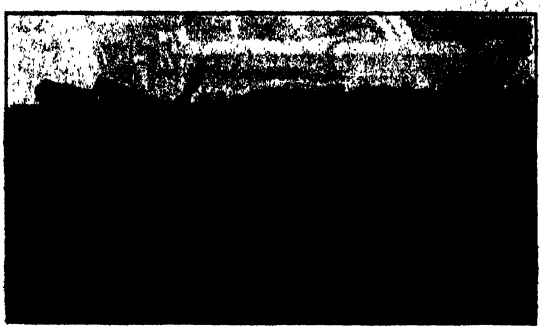

FIG. 18.—German 105-mm. field howitzer, 1898–1909.

The U.S.A. likewise had no light field howitzer, and in the war its divisional artillery consisted of French 75-mm. guns and 155-mm. howitzers. The 100-lb. shell fired by the latter is too heavy to be transported in sufficient numbers for a divisional field howitzer, and the U.S.A. is now bringing out a 4·2-in. (105-mm.) howitzer to fire a 33-lb. shell, M.V. 1,500 f.s., to range 12,000 yd. The howitzer is about 25 cals. long, and weighs 11½ cwt. It has hydro-pneumatic controlled recoil on the St. Chamond system; the recoil is decreased from 45 in. at zero elevation to 33 in. at 80 degrees. The carriage has a split trail and gives 30° traverse; it has a high shield. The wheels have rubber tires to allow it to be drawn by a tractor at 10 m. an hour without injury. The weight in action is 33 cwt. This piece is also mounted on a caterpillar automobile carriage.

The pre-war German field howitzer (fig. 18) was of 105 mm. (4·2 in.) cal., firing a 34-lb. shell to a range of 7,600 yd. It had rear trun-

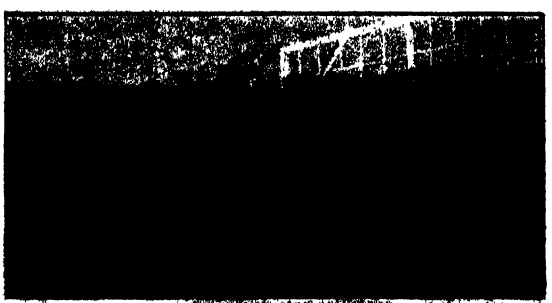

FIG. 19.—German [illegible] howitzer, 1916.

nions and balance spring, which in this case was not a satisfactory arrangement as the spring was liable to give an electric jar, causing bad shooting. In 1916 the Germans increased the length of the piece from 12 to 22 cals., with a corresponding increase of the weight in action from 22½ to 27 cwt. The lengthened howitzer, shown in fig. 19, ranged 9,200 yd. with ordinary shell and 10,500 yd. with streamline shell. It was rear-trunnioned like its predecessors.

The field howitzers used by the other nations were mostly similar in power to the Schneider 4·2-in. field howitzer mentioned above.

*Horse Artillery Guns.*—These are at present in a stage of arrested development, pending further experience with motor guns. A horse artillery gun must be capable of keeping pace with cavalry on the road and across country, and it is as yet uncertain whether the horse-drawn gun, the motor-drawn gun, or the gun on automobile carriage is best adapted to the purpose.

The British 13-pdr. horse artillery gun was a small edition of the 18-pdr.; the French and the Russians had similar guns, namely, Schneider guns weighing about 19 cwt. in action. The French gun fired the same ammunition as the 75-mm. field gun, with one-third

of the powder charge withdrawn. The Germans used their "96 n.A." field gun, with slight modifications, as a horse artillery gun.

*Mountain Guns.*—Even before the war, the principal gun-makers produced 15-pdr. mountain guns light enough for pack transport, namely, with the heaviest top load not exceeding 250 lb. net. However, the guns used in the war were mostly 11-pdr., though the Greek Schneider-Danglis gun was a 14·3-pdr. The British pre-war mountain gun was a 10-pdr., and a 12½-pdr. was issued in 1914. It is now considered that a mountain gun should fire a 15-lb. shell, and new equipments are under trial in several countries. The new U.S.A. equipment is styled a mountain howitzer, and is described below.

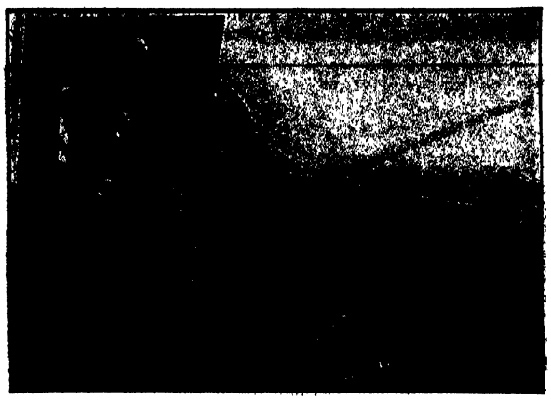

FIG. 20.—British 3·7-in. mountain howitzer.

The British 12½-pdr. mountain gun is in two pieces, joined by a nut; its calibre is 2·75 in. It fires a bare charge, not fixed ammunition, and its range is 5,800 yd. at 15° elevation. The carriage has a cranked axletree, which can be revolved to bring the cranked portion uppermost when firing, to allow room for the gun to recoil. The buffer and running-up springs of ordinary pattern are contained in the trough-shaped cradle; the top of the cradle is closed by the "slipper" (corresponding to the Krupp "sleigh") which slides on the cradle-guides during recoil and run-up. The gun when put together is secured to projections on top of the slipper. This gun will be replaced by a 15-pdr. on the same lines as the new U.S.A. mountain equipment, fitted for draught as well as pack carriage.

*Mountain Howitzers.*—These are subject to the same limitations of pack loads as mountain guns, but have to be heavier as a whole in order to fire a shell weighing 20 to 25 lb. The extra weight is obtained by increasing the number of loads. A good specimen of pre-war equipments is the British 3·7-in. mountain howitzer, which is noteworthy as being the first split-trail equipment introduced into the British service (see fig. 20). It fires a 20-lb. shell and ranges 5,800 yd. The howitzer is in two parts. It has controlled recoil gear similar to that of the 4·5-in. field howitzer described above. The equipment forms 8 mule-loads.

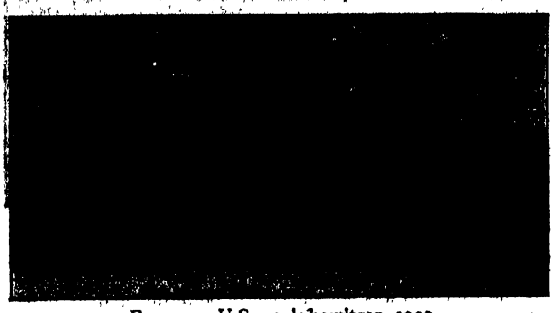

FIG. 21.—U.S. pack howitzer, 1920.

A more modern specimen is the 1919 French Schneider 105-mm. (4·2-in.) mountain howitzer. This is a 26·4-pdr. ranging 9,000 yd. at 49 degrees. Unlike the British mountain guns, it is not divided halfway down the bore; the division is in rear of the powder-chamber. The gun, 13 cals. long, consists of the barrel and the breech-piece, the latter being prolonged into a jacket which fits loosely round the gun and serves the purpose of increasing the recoiling weight so as to reduce the recoil. This construction has been used in the Greek Schneider mountain gun and has stood the test of war. The cradle is of the same length as the gun, and contains the ordinary Schneider hydro-pneumatic gear, charged with compressed nitrogen instead of compressed air. The gun recoils on a slipper as in the British mountain gun. The cradle trunnions are set far to the rear, giving a forward preponderance, but no balance spring is used; the height of the line of fire is 31 in. with 36-in. wheels, and this gives room for the full recoil of 33½ in. at 40° elevation without the breech striking the ground. The piece traverses on the axle as in most French equipments, and the total traverse is 160 mils or 9·6 degrees. Six of the seven pack-loads are above the 250-lb. limit observed in the British and American services.

The U.S.A. pack howitzer, Model 1920, fig. 21, replaces the U.S.A. mountain gun. It fires the same 15-lb. shell as the field gun, M.V. 900 f.s., ranging 6,600 yd. It has the St. Chamond recoil gear referred to above. The howitzer has rear cradle trunnions and balance spring, the latter being a torsion spring coiled round the axle. The carriage is on 29-in. wheels and gives 45° elevation and 2½° traverse, but a split-trail carriage is under trial. The howitzer and carriage form 4 loads of 235 lb. net. This equipment is to serve as a gun of accompaniment as well as a mountain gun, in addition to the "infantry howitzer" described below.

*Guns of Accompaniment.*—These are required to accompany the infantry, to deal with machine-guns and strong points that have escaped the barrage, and to protect the infantry against tanks that may attack them. The necessity for some form of gun of accompaniment was generally recognized during the last two years of the war; in the absence of specially designed weapons the infantry used anything they could get. Thus the German infantry used their field gun on 3-ft. wheels, captured Russian horse-artillery guns, field guns on semi-mountain carriages borrowed from the artillery, German and Russian mountain guns, light trench-mortars adapted to direct fire, and German 57-mm. 6-pdr. Hotchkiss guns. The British used the few 3·7-in. mountain howitzers available, the 6-in. Newton trench-mortar on an improvised carriage, and captured German light trench-mortars. Further, the British detailed sections of 18-pdr. and the Germans batteries and sections of 77-mm. field guns to accompany the infantry.

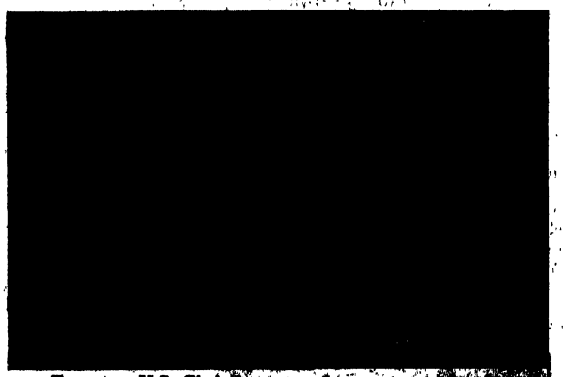

FIG. 22.—U.S. Christie reconnaissance tractor [illegible]

The Germans brought out a gun of accompaniment [illegible]8, but only a few were ready in time to take part in the fighting. This was the "*infanteriegeschütz 18*," a reduced copy of the [illegible] field gun, and capable of firing the same 18-pdr. ammunition [illegible] part of the charge withdrawn. The length was 93 cals. against [illegible] for the field gun; the M.V. was 1,870 f.s. and extreme range 7,500 yd. The weight in action was 15·7 cwt. This weapon seems to be not powerful enough for use as a light field gun, and not mobile enough for an infantry gun; it was a compromise to which the Germans resorted in preference to introducing a new calibre and complicating their ammunition supply. The Germans have shown no desire to retain this gun in the small pieces [illegible] by the Peace Treaty.

The only pattern [illegible] accompaniment under the [illegible] Infantry Howitzer. It is [illegible] a 6-lb. H.E. shell for direct fire, M.V. 700 f.s., and a 10-lb. shell for curved fire. This piece is to supersede the 37-mm. infantry gun used by the French and Americans during the war, and to supplement the 15-pdr. pack howitzer. It is mounted on a wheeled carriage with cranked axle, which can be turned inwards when the piece is used for curved fire. The equipment is divisible into man-loads, the heaviest —the howitzer itself—weighing 80 lb.; this is carried by two men. The total weight is 300 lb. The howitzer is to be taken forward as far as possible by a Christie motor-cart (fig. 22), a small cross-country vehicle weighing only 660 lb.; thence the howitzer is run forward by hand, and the cart follows with ammunition.

*Medium Guns.*—Medium guns are long-range guns sufficiently mobile to march with an infantry division and to come into action in support of the infantry without any preparation such as building platforms. In the British service the medium gun is the 60-pdr., weighing about 5 tons and drawn by a team of heavy horses. The first model of this was a very useful gun in its time, and was remarkably accurate; it fired both shrapnel and H.E. shell, and ranged 10,000 yd. A new pattern with under-cradle was issued in 1918, which ranged 15,000 yd. with a pointed shell with 8-calibre head. The Germans had the 15-cm. (5·71-in.) gun of 1910, which threw an 86-lb. shell 15,700 yd., as well as various patterns of 10·5 cm. Their pre-

war 10·5-cm. (4·13-in.) medium gun was 30 cals. long and ranged 12,200 yd. Their 1914 pattern was 35 cals. long, range 14,300 yd.; and their 1917 pattern was 45 cals long, range 21,300 yd. with false cap. It was on a field carriage of simple construction, with 4 ft. 4-in. wheels, resembling an enlarged field gun. It had rear trunnions, variable recoil (95–155 cm.), air recuperator and pivot traverse. The carriage gave 45° elevation. The weight was about 3½ tons.

In the World War, all parties used medium guns of 10-cm. (4·2-in.) and 12-cm. (4·7-in.) calibre. These were largely not model guns belonging to siege trains and fortress armaments but some powerful naval guns and also some new models (*e.g.* the French 105-mm. of 1913) were amongst them. Since the war a few types have been brought out, but for the reason mentioned below the history of the medium gun seems to be closed.

FIG. 23.—British 60-pdr. gun.

The French (St. Chamond) carriage for 4·7-in. guns or 6·1-in. howitzers is noteworthy as a successful attempt to simplify equipment by using one pattern of wheeled carriage which will take either a medium gun or a heavy howitzer. The carriage has hydro-pneumatic recoil gear of the "floating" piston class. The recoil is controlled, *i.e.* automatically shortened at high elevations to prevent the breech of the gun from striking the ground. This is effected by throttling the passage through which the liquid passes from the buffer to the compressed-air reservoir, by means of a valve actuated, through the left cradle trunnion, by a cam attached to the carriage. The relative motion of the cradle with regard to the carriage, as the gun is elevated, partly closes the valve. This is the gear which has been adopted for several of the new U.S.A. equipments, as mentioned above. It is simple and efficient, and is better adapted for mass production than the pattern in which the recoil is controlled by revolving the buffer piston.

FIG. 24.—German 10-cm. gun, 1914.

The 4·7-in. gun and 6·1-in. howitzer made by the St. Chamond firm have the Canet "revolving block" breech action and have rear trunnions, the forward preponderance being held up by a pneumatic balance spring. In other respects the wheeled carriage is of the ordinary construction. Since the gun, or the howitzer, weighs only 3·46 tons in action, it can be transported on its own wheels by a team or a tractor. However, to increase its mobility, it is usually transported in two loads, the gun travelling on a special wagon.

Although medium guns have been of great service in the past, it seems doubtful whether any more of them will be made. They represented the maximum power, subject to the limitations of horse draught, that was compatible with mobility sufficient to march with an infantry division. With the advent of mechanical traction, they are likely to be superseded by the far more powerful 6-in. gun.

*Medium Howitzers.*—During the period of trench warfare, the principal weapon employed by both sides was the 6-in. howitzer, throwing a shell of 95 to 100 lb. This was capable of penetrating the strongest artificial cover commonly met with in the trenches, and nothing short of a semi-permanent concrete structure was proof against it. Practically all belligerents employed weapons of this class, both old models (adapted to new mountings or left on their old carriages) and new. In 1914 the British had none of these pieces except a few of the old siege howitzers described and illustrated at 20.224, but the 6-in. Q.F. howitzer designed in January 1915 began to be issued in the latter part of the same year, and by the end of the war 3,633 of these had been delivered. It proved a serviceable weapon, though far inferior in power to those made since the war, as its weight was restricted by the limitations of horse draught, and was only 86 cwt. It ranged 10,000 yd. with a 100-lb. shell, or 11,600 yd. with the streamline shell afterwards introduced. The carriage was of simple construction with a long cradle. Future equipments of this nature will be made with a split trail to avoid the delay incurred by traversing such a heavy piece.

FIG. 25.—German 10-cm. gun, 1917.

The French in 1914 had only 105 mobile 6-in. howitzers. These were of the Rimailho pattern, designed by Commandant Rimailho, who like Deport had been one of the creators of the 75-mm. gun This piece was remarkable in its day as being the first medium howitzer designed to be drawn across country by a team of horses at a trot. This degree of mobility was secured by conveying the howitzer itself on a special light wagon, while the carriage travelled empty. This wagon formed a slide which could be adjusted in prolongation of the cradle, so that the piece could be shifted from one to the other by means of a winch, an operation which took only ten minutes. Other features which were then novel were a semi-automatic breech mechanism actuated by the recoil, an automatic loading system in which the shell and cartridge were driven home by the breech block, elaborate sight mechanism, and rear trunnions with a pneumatic balance spring. The wagon with the piece weighed 2·75 tons, and the

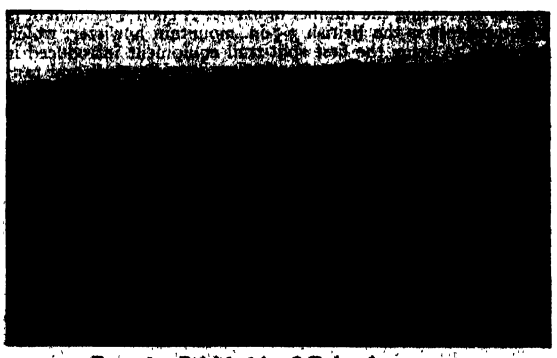

FIG. 26.—British 6-in. Q.F. howitzer, 1915.

empty carriage 2·5 tons. The extreme range was 6,500 yd., as the piece itself was an old model.

As the Rimailho was not sufficiently powerful, and as only 105 existed, Schneider and St. Chamond weapons of the same class were brought in to replace it. The powerful Schneider 155-mm. (6·1-in.) howitzer throws a 95-lb. shell, M.V. 1,500 f.s., to a range of 13,300 yd. The peculiarity in its construction is the counterweight on top of the breech. This was added in order to enable the makers to get a greater length of the piece forward of the trunnions while maintaining a breech preponderance. In ordinary times they might have put in a pneumatic balance spring,[1] but in war-time the simpler expedient was preferred.

[1] Balance springs and pneumatic equilibrators are introduced to take the weight of the gun and cradle when trunnioned behind the centre of gravity. This rear trunnioning is necessary with long-recoil high-elevation guns because, if the cradle were on central trunnions so as to balance the gun, then, when elevated, the breech would strike the ground on recoil. But this gives the gun a heavy muzzle preponderance which has to be balanced. The usual method was

The original model of 1915 was altered in 1917 to take a bare charge, owing to shortage of brass for cartridge cases; this involved the use of an obturating breech mechanism and added 55 lb. to the weight. The ballistics remained as before.

The 155-mm. howitzer is transported on its own wheels with a limber fitted for horse draught, or may be limbered up to a tractor. It travels in the extreme recoil position to distribute the weight. The weight in action of the 1917 pattern is 3·3 tons, and the weight with limber 3·7 tons, so that it is sufficiently mobile to accompany troops. It can if desired be divided into two units weighing 2·5 tons for the howitzer and 2·6 tons for the empty carriage. It was used by both the French and the Americans as part of the divisional artillery.

FIG. 27.—German 15-cm. heavy field howitzer, 1913.

The U.S.A. 155-mm. (6·1-in.) howitzer, 1920 model, is 24½ cals. long, and fires a 95-lb. shell, M.V. 1,850 f.s., ranging 16,000 yd. The carriage has a plain trail, and gives 65° elevation and 10° traverse on the axle. It has hydro-pneumatic controlled recoil gear. A split-trail carriage giving 60° traverse is also being tried. This piece is an example of the changes made in howitzer equipments since 1914. The 6-in. howitzer of that date was some 12 cals. long, M.V. 950 f.s.; the modern howitzer is twice as long and has double the muzzle velocity and double the range, and would formerly have been classed as a gun.

FIG. 28.—German 15-cm. howitzer, long pattern, 1913.

The German 15-cm. (5·9-in.) howitzer, 1902 pattern, was a light horse-drawn weapon weighing only 44 cwt. in action. It fired a 95-lb. shell and ranged 7,000 yd. It was 14 cals. long, of ordinary Krupp pattern with variable recoil, and the carriage gave elevation up to 45° in order to obtain a steep angle of descent at short ranges.

for this, a pair of compression springs set forward of the cradle trunnions. The action of these is not very satisfactory, as if the thrust of the springs be sufficient to support the gun at a high elevation, when the spring is fully extended, then it is excessive at a low elevation. Telescopic springs were used in the Krupp mountings to give a more uniform thrust. But these balance springs are now being superseded by a compressed-air "equilibrator." This device, in principle, was used in the French Rimailho howitzer; in its present form it was first brought out in the British Armstrong railway mountings, and has since been adopted for caterpillar mountings. It consists of two steel tubes fitting one into the other, the outside ends of the tubes being closed. The telescopic vessel thus formed is filled with compressed air, which tends to force the tubes apart. It is prevented from escaping by a double packing, with a recess beween the two packings which is filled with grease, constituting a "grease seal." The compressed air gives a more regular thrust than a spring, and can be connected to the cradle with suitable leverage so as to balance the gun at every elevation. The gun can then be elevated and depressed by the handwheel with comparatively slight effort. When the compressed-air equilibrator is used in the heavy railway mountings described later, the construction is slightly different; the telescopic vessel is filled with oil or glycerine instead of air, and is connected by a tube to a reservoir of compressed air so that the air has no access to the packings. The reservoir is of such a size relatively to the cubic contents of the equilibrator as to give the desired variation of thrust at different elevations. This gear is known as the "hydro-pneumatic balance spring."

The 1913 pattern gave somewhat better ballistics; this had rear trunnions and balance spring, and was 14 cals. long; it had an air recuperator. This was superseded by an improved pattern, 17 cals. long, giving M.V. of 1,270 f.s. and a range of 9,400 yd. with 95-lb. shell. This howitzer fired without a platform, using mats under the wheels in soft ground. It weighed about 61 cwt. in action, and was easily transportable. Though inferior in power to the French 155-mm., it was an excellent weapon, and was the principal piece employed by the Germans in trench warfare, besides being mobile.

*Heavy Guns and Howitzers. The 6-in. Gun.*—The authorities of all the military nations concur in considering this gun as one of the most important types used in land as well as in naval warfare. The

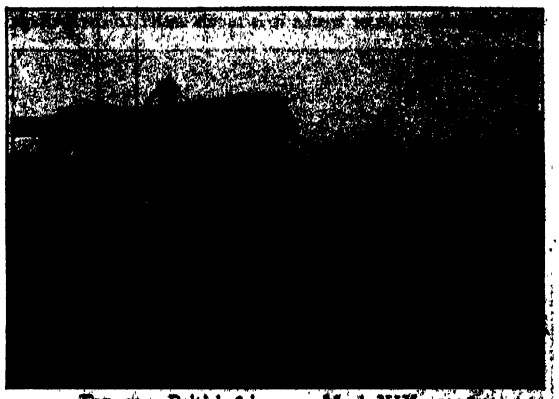

FIG. 29.—British 6-in. gun, Mark XIX., 1916.

pattern developed in the latter part of the war throws a shell of 100 lb., containing 12 lb. of H.E., a distance of 15 m. The shell, while not too heavy for transport or handling, is powerful enough to do great damage to buildings, bridges, and similar targets, and it is practically impossible to build cover proof against it without recourse to armour plates or masses of concrete.

At the beginning of the war the British had no 6-in. mobile guns. The Mark VII. 6-in. was taken from coast defence and mounted on a simple carriage with traction-engine wheels. On firing, the carriage ran back up inclined planes, and ran forward again into position. This gun ranged only 17,700 yd. In 1916 a later pattern, Mark XIX., was mounted on the 8-in. howitzer carriage, with cradle and buffer (fig. 29), which much increased its rate of fire. The 6-in. Mark XI. naval gun, a much more powerful weapon, was on a railway mount similar to those described below.

The Germans, in addition to old-model siege guns, had a 15-cm. naval gun, 40 cals. long, mounted with its naval ring cradle and short-recoil buffers on a heavy-wheeled carriage. This was replaced towards the end of the war by the 1916 pattern, 43 cals.

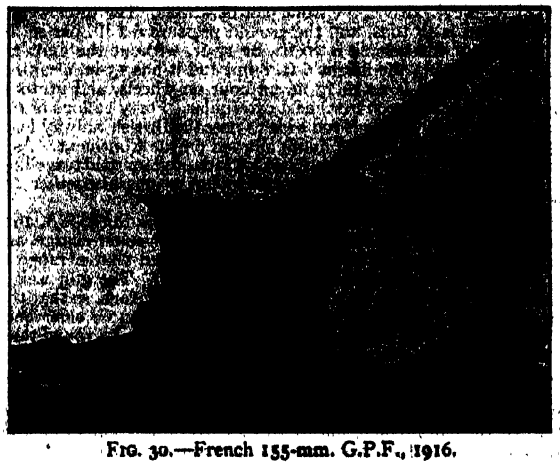

FIG. 30.—French 155-mm. G.P.F., 1916.

long, which had a maximum elevation of 42° and range of 25,000 yd. There were two patterns; in the lighter the weight of the gun unit in travelling was 6½ tons, that of the carriage unit 5½ tons. In action the gun and carriage weighed 9½ to 10 tons according to mark. Beds were provided for soft ground.

The French, after using up the 6-in. de Bange guns of their fortresses on various mountings, old and new, and bringing in naval and other guns of 14, 14·5, 15·5 and 16 cm., adopted as standard the design of Colonel Filloux known as the 155-mm. (6·1-in.) G.P.F. (*grande puissance Filloux*). This gun, which was also used by the

Americans, was a longer gun, namely 38 cals., throwing a 100-lb. shell, and ranged nearly 20,000 yd. with streamline shell. The French had a variety of automobile and tractor-drawn mountings for this gun. One of the latter had a split trail, giving 60° of traverse; to transport it, an extra pair of wheels was placed under the point of the trail, and the gun run back so as to divide the weight between the two pairs of wheels. In another form the gun was carried on a motor lorry. In 1918 the French used a 10-ton Renault caterpillar tractor with the gun mounted on it for all-round fire. This was a powerful machine with 110-H.P. motor. It carried outriggers which were fixed when the gun fired across the vehicle. One object of putting an all-round mounting on a caterpillar, which itself can be easily turned about, is that when the gun is in a position where it has to stay for days or weeks it is much easier to camouflage a

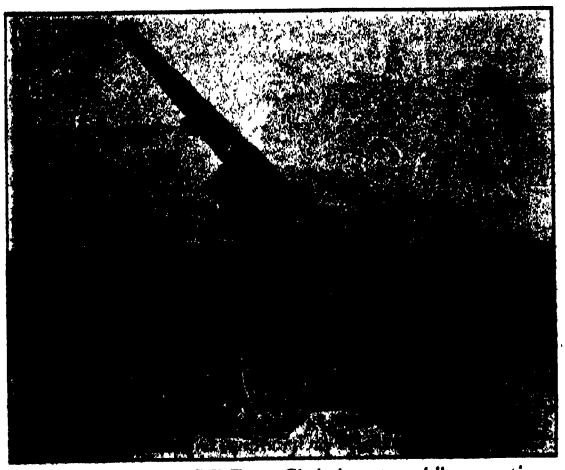

FIG. 31.—155-mm. G.P.F. on Christie automobile mounting.

mounting which does not have to be shifted to lay the gun. Such a mounting can be sunk in the ground, or a protecting roof can be built over it. At the end of the war a number of St. Chamond automobile mountings with electric drive from a power trailer were under order for the 155-mm. gun. An enlarged G.P.F. of 104 more calibre was brought out and used towards the end of the war.

Fig. 31 shows the 155-mm. G.P.F. on Christie automobile mounting. This has 8 double-tired wheels with 36" x 6" tires. The two front wheels are fixed, the two rear wheels pivoted for steering. When working as a wheeled carriage, on the road, the two centre pairs of wheels are raised off the ground; when used as a caterpillar, with a "track" round the four wheels on each side, the centre wheels are let down so as to take their share of the load; the vehicle is then steered by varying the relative speed of the two tracks. The engine (120 H.P., 6-cyl.) drives the front pair of wheels. The total weight with the gun is 17 tons, and the ground pressure 6·1 lb. per sq. in. The length of the vehicle is 20 ft., or 17 ft. without the gun; the width is 9 ft. 4 in., the height 6 ft. 8 in., and it has 13-in. clearance under. The speed is up to 17 m. an hour on wheels, and up to 12 m.p.h. (or 14½ if beech first) as a caterpillar. Forty gallons of fuel are carried. This vehicle is too wide to pass the British railway loading gauge, but is within the limits allowed on the Continent. As it weighs only 17 tons with the gun, it is well adapted for road travelling.

The same gun on an ordinary caterpillar weighs altogether 27½ tons, and its road speed is 3 m. an hour.

A good example of the after-war 6-in. gun is the U.S.A. 1920 model, which is 45 cals. long, M.V. 2,800 f.s. with super-charge, and ranges 26,000 yd. with 100-lb. shell. It is stated that a range of 30,000 yd. can be obtained with false tail shell. The gun weighs 79 cwt., and the weight on wheeled carriage is 30·7 tons, so that this gun cannot be transported by horse draught. It can on emergency be fired from its own wheels, with girders of linked plates round them to increase the bearing surface, but for continuous fire it requires a platform, or it will probably be used practically on a railway mounting.

A long gun of these characteristics may be looked upon as approaching a limit, both as regards travelling and as regards firing. At about the calibre of 17 cm. begins a class of long guns which requires a platform for firing and sub-division for travelling. Both platforms and sub-division may be and frequently are desirable at the 6-in. level, but beyond it there is no choice in the matter so far as wheeled mountings are concerned. At the level of war-time 17-cm. and post-war 15-cm. long guns commences also the class of all-round railway mountings to be described presently.

The provision of platforms formerly caused considerable delay in opening fire; a wooden platform is suitable only for field and medium guns and a concrete platform takes at least a month to set before it is ready to fire from. "Caisson" platforms consist of cellular boxes of iron plate which are sunk into the ground, bolted together on the spot, and filled with concrete or in some cases merely with earth. Since the concrete is used chiefly to weight the platform, it is not necessary to wait till it has set hard. When the gun is moved to another position, the caisson platform is abandoned, with the exception of the top plate carrying the fittings for the attachment of the gun-mount. During the course of the war these platforms were improved so as to afford support only where required, and so to require less excavation. For this purpose the caissons were made of special shapes, as afterwards described. They were known as "earth-boxes," and in some instances they were not even buried, but erected on the surface of the ground. In some cases the gun or howitzer remains on its travelling wheels for fire, in others it travels in parts and is assembled on the platform.

*The German 17-cm. (7-in.) Gun.*—This was a 40-cal. naval gun, throwing a 140-lb. shell, M.V. 2,500 f.s., to a range of 30,000 yd. The gun weighed 10·8 tons. Some of these pieces were used on railway mountings, others were fitted for road transport. The gun was mounted, in its naval cradle, on a carriage of ordinary field construction, with massive broad-tired steel wheels 6 ft. in diam. The platform from which it was fired consisted of five "caissons" or steel boxes, buried in the ground in the form of a cross. The fifth caisson, which bore the pivot, was in the centre of the cross and connected the four arms together. A horizontal framework with a pair of steel girders extended back from the pivot; the gun wheels rested on plates fixed to these girders on either side of the pivot, and the trail abutted against the cross-piece connecting the rear ends of the girders. The whole girder frame, with the gun and carriage, could be revolved about the pivot when it was required to traverse the gun through a large angle; for angles up to 5° each way the carriage could be traversed within the girder frame by shifting the trail along the cross-piece. The rate of fire was one round per minute. The equipment was easily transportable by road in 3 loads, namely, gun on special wagon, carriage, and platform.

This was a powerful long-range gun which could travel by road or rail and could come into action and open fire within 48 hours. The railway mounting for this gun was the same as the platform mounting, and the same horizontal girder frame was used, mounted on a railway truck instead of a caisson platform. The traverse obtainable was 26 degrees.

The French Schneider 220-mm. (8·66-in.) gun, model 1917, was used in the war with a road-mobile mounting, and has since been mounted on a caterpillar automobile carriage. The gun is 35 cals. long and weighs 9½ tons; it ranges to 24,500 yd. with a 200-lb. streamline shell, M.V. 2,580 f.s. It is fitted with double recoil, having both a cradle system (nitrogen recuperator) and an upper-carriage system which recoils against gravity and a buffer.

The road-mobile mounting was sub-divided into two loads, but could be moved as a unit for a short distance. In the firing position the gun, cradle, upper carriage and lower carriage rested on a platform (which was permanently fixed to the lower carriage). The platform was pegged down in rear and connected to an earth anchorage in front. The lower carriage was pivoted to the platform and could be traversed 25° each way. The weight in action was 25 tons exclusive of the anchorage, and the travelling loads were 16 tons for the carriage and platform unit and 14 for the gun unit.

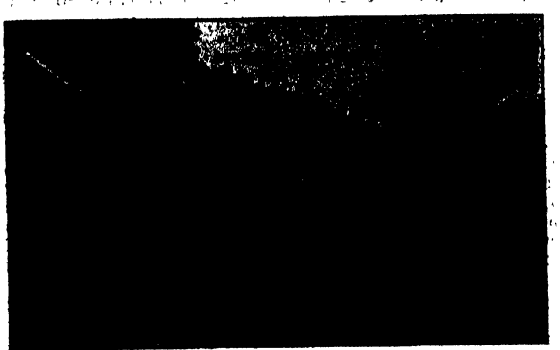

FIG. 32.—French 220-mm. Schneider, caterpillar carriage.

The gun on caterpillar carriage is shown in fig. 32. The upper carriage is supported on rollers with springs, and recoils on a slide, so that there is a double system of recoil gear. The upper carriage gives 37° elevation; traversing is effected by turning the whole mounting by means of the caterpillar tracks, which are worked by a 10-H.P. auxiliary motor.

The caterpillar carriage is 26 ft. long, or 35 ft. including the muzzle of the gun in travelling position; the width is 9 ft. and height 10 ft. The road speeds are from 1 m. to 5 m. an hour; the low gear is very powerful, and the caterpillar will climb a slope of 1 in 2. The weight of the gun and carriage is 14 tons, caterpillar 26 tons, total 40 tons. This is too heavy for road bridges, but the weight and dimensions are such as just to admit of its being carried on a French 40-ton railway truck. The height and width are in excess of the limits of British railway loading gauge.

This mounting marks about the limit of possible weight for an automobile gun-carriage. In fact, it is only fit to travel by rail to a point near its destination, and thence to travel by main roads and across country, avoiding by-roads and country bridges. It may be noted that the 60-pdr. gun-carrying caterpillar tried by the British weighed 35 tons with the gun and had to be discarded as too heavy. The ordinary road bridges of a country, other than those on the main "national" roads of western Europe, will not carry more than about 20 tons, and ordinary road culverts are liable to be crushed. The simplest solution of the difficulty is to transport the gun and carriage separately, as with the German 15-cm. 43-cal. gun.

*The 8-in. Howitzer.*—Early in the war it was found necessary to introduce for field service a howitzer firing a shell of about 200 lb., for the destruction of fortified buildings, railway stations, and bridges. Non-mobile weapons of this class were already in existence

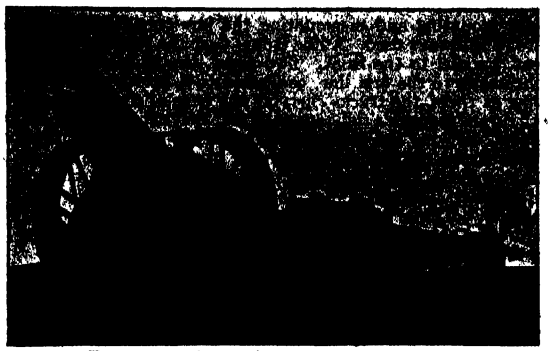

FIG. 33.—British 8-in. howitzer, Mark VII.

as siege pieces, and these were employed with modified mountings, as a makeshift. But the Germans in particular had developed wheeled mountings for 21-cm. "mortars," and the appearance of these as mobile heavy artillery obliged the Allies to follow suit.

The British at first issued an old-pattern 6-in. gun with the muzzle cut off, bored out to 8 in.; this was superseded by the Mark VII. 8-in. howitzer shown in fig. 33. Some of these British pieces were used by the French and Americans. The howitzer was 18·5 cals. long and weighed 69 cwt., or 10·3 tons on wheeled carriage. It was an enlarged edition of the 6-in. howitzer, and ranged 12,500 yd. This piece could be transported by road, the carriage travelling empty; this weighed 6·8 tons. A platform was provided for use in soft ground. The Americans, when they adopted this piece, mounted it on an automobile carriage (which also took the 6-in. gun) made by putting the upper carriage of the howitzer on an 80-H.P. Holt caterpillar. This mounting gives 45° elevation and 8° traverse, and weighs 26 tons complete. The road speeds are 1 to 4 m. an hour.

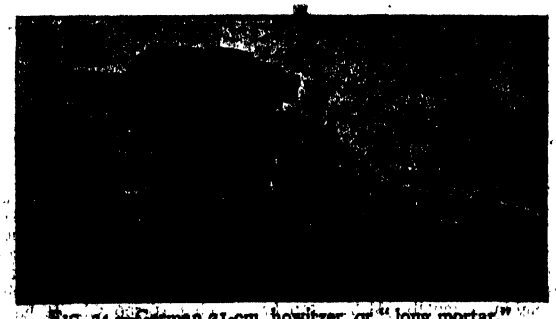

FIG. 34.—German 21-cm. howitzer, or "long mortar."

The U.S.A. 1910 model 8-in. howitzer is more powerful than the British Mark VII. It is 25 cals. long and weighs 80 cwt.; it fires a 200-lb. shell, M.V. 1,050 f.s., ranging 18,000 yd. The wheeled carriage, which also takes the 6-in. gun, gives 65° elevation and 10° traverse on the axle; it has variable controlled recoil, the full recoil being 6 ft. The elevating gear consists of 2 toothed arcs which can be released from the cradle trunnions so that the howitzer can be swung to the horizontal position for loading. The weight is 21 tons.

The French had no mobile 8-in. howitzer before the war. They issued a certain number of 19-cm. guns bored out to 8-in. calibre (not cut short) to fire British 8-in. ammunition. These guns on high-angle carriages made good long-range howitzers and were used on railway mounts, but were too heavy for road transport. For a mobile piece the French introduced the Schneider 22-cm. (8·27-in.) siege howitzer, 13 cals. long, firing a 216-lb. shell, M.V. 1,180 f.s., and ranging 9,600 yd. The method of transportation was peculiar to the French artillery, the howitzer itself being fitted with split wheels and 4 parts instead of being carried on a special weight like the German heavy howitzers. The howitzer with wheels weighed only 2¼ tons, and the empty carriage 3¼ tons, making loads which could be transported by horse draught or by a small tractor. This howitzer is fired from its wheels, and can be fired from the bare ground, but requires a platform for continued fire.

The German 21-cm. (8·3-in.) howitzer, styled a "mortar," was of several patterns. The very earliest fired from a bed, but the pieces which played a conspicuous rôle in the war were the ordinary or short mortar 12 cals. long, which ranged 9,800 yd. with 265-lb. shell (M.V. 1,120 f.s.), and the long mortar was 15 cals. long and ranged 11,200 yd. with 261-lb. pointed shell. The recoil gear consisted of 2 oil buffers and an air recuperator, placed above the piece, allowing 43-in. recoil. The carriage gave 70° elevation and 4° total traverse. The short mortar weighed 2·6 tons, the long pattern 2·8 tons; the weights in action were 6·3 and 6·5 tons respectively.

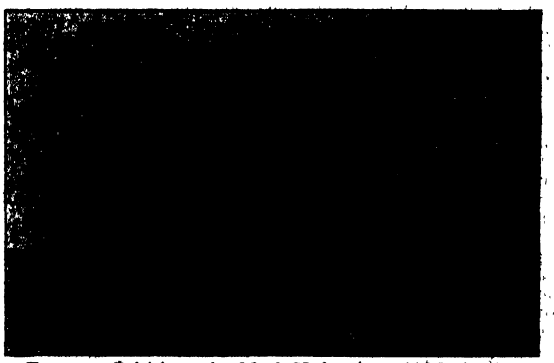

FIG. 35.—British 9·2-in. Mark II. howitzer ("Mother").

*9·2-in. and 9·45-in. Howitzers.*—The British 9·2-in. howitzer was a pre-war design, and the first of these equipments were sent to France in November 1914. Fig. 35 shows the general construction. It fired a 290-lb. shell ranging 10,000 yd., but with a pointed shell a range of 12,700 yd. was afterwards obtained. This was the first British equipment to be provided with a floating piston.

The howitzer was 14·6 cals. long and weighed 3·1 tons; the carriage weighed 5·3 tons, but this weight could be reduced for travelling by carrying the cradle separately. This wheeled mounting allowed the howitzer to be fired at angles between 15 and 45° elevation. This feature, namely, restricting the fire to the higher angles of elevation, is found in most heavy howitzer equipments on wheels; the object is to avoid the extra weight and extra length of recoil which would be necessary to keep the carriage steady if the howitzer were fired point-blank. The howitzer traversed on the axle, 2½° either way. It could be fired from the bare ground, but a platform was generally laid for it. Some of these howitzers were mounted on beds instead of

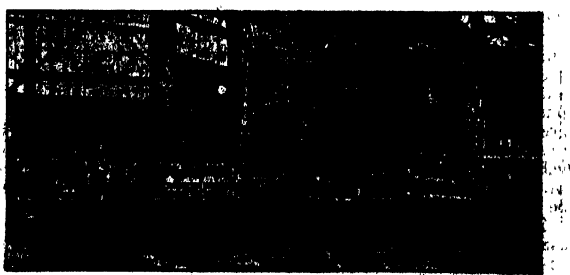

FIG. 36.—U.S. Mark IV. carriage for 9·45-in. howitzer.

firing from their wheels; the platform for these had a pivot in front, an arc in rear to support the rear of the bed, and a pit into which the breech of the howitzer recoiled.

The true 240-mm. howitzer was not much used in the war; it is an intermediate piece which lacks the shell-power of the larger calibres and is nearly as troublesome to transport and to emplace. However, the U.S.A. has a new howitzer of this calibre, 36 cals. long, M.V. 2,350 f.s., which ranges 25,000 yd. with 356-lb. shell. This is really a gun, though called a howitzer. Many old, short naval guns of this calibre were used by the French during the war practically as long howitzers.

A very interesting automobile mounting for a 240-mm. howitzer was brought out by the French firm of St. Chamond during the war. This consists of a caterpillar mounting drawing a power trailer behind it. The trailer carries a petrol engine and dynamo which supplies current to the electric motors, both of the mounting and the trailer. These two may be connected mechanically and electrically, or electrically only by a cable. Thus if the drawbar be disconnected the trailer may remain behind under cover and drive the gun

mounting forward as far as the cable extends; 500 metres of cable can be carried, though only 50 metres are normally used. The advantage of this system is that the gun-mounting is simplified and lightened by the absence of the motor, and that it is easier to find room for the gun between the sides of the mounting. The trailer carries a load of ammunition nearly equal in weight to the gun.

The most recent equipment of this type is the U.S.A. Mark IV. carriage for the 1918 pattern 9·45-in. howitzer, built to St. Chamond designs. The trailer carries a 150-H.P. petrol engine driving a 70 K.W. 400-volt compound-wound dynamo, which supplies the current to 2 independent 400-volt motors, each driving one track of the gun-mount, and to similar motors on the trailer.

This howitzer is 21¼ cals. long and fires a 356-lb. shell ranging 17,500 yd.; it weighs 97 cwt. The mounting gives 60° elevation, but no traverse; this is given by traversing the whole caterpillar mounting with a small auxiliary motor. The mounting is 30 ft. long, 8 ft. 6 in. wide, and 13 ft. high, including the ammunition crane. It weighs 13 tons complete; the trailer is of the same size and weight, and carries 42 rounds of ammunition. The average speed of the combination is 6·5 m. an hour.

This type of power-trailer mounting has great capabilities, but has not been tried thoroughly enough to warrant its general acceptance. It would appear difficult to steer across bad ground when mechanically connected; however, there is the possibility of sending the gun-mount forward across a bad place, and then halting it while the trailer follows. One advantage claimed for it is that the trailer can be used to bring up ammunition while the gun is in action.

*Super-heavy Guns and Howitzers.*—The British regulations now apply this term to all guns heavier than the 8-in. and all howitzers heavier than the 9·2-in. Super-heavy pieces are now fired almost exclusively from railway mountings, and therefore are not transported by road. The Germans in 1914 transported 11-in., 12-in. and even 16½-in. howitzers by road, but the increased range of modern pieces of this calibre renders it possible to bring them up by rail to within effective distance of any target that they are likely to be required to engage. The types of super-heavy, road-travelled equipments evolved during the World War were very numerous, and only certain representative models can be described.

FIG. 37.—Austrian 12-in. howitzer on its way through Belgium.

*The 11-in. Howitzer.*—The Krupp 28-cm. (11-in.) howitzer was brought out in 1912. It was remarkable in its day as being the heaviest weapon that could be fired from its wheels without a permanent platform. This was due to the long recoil of 6 ft., and to the weight of the howitzer itself, which reduced the recoil-energy. Girdles of linked plates were fixed round the wheels to enlarge the surface bearing on the ground, and mats of sandwiched layers of wickerwork and steel plates were laid under the wheels. The howitzer fired a 750-lb. shell ranging 11,200 yd., M.V. 1,130 f.s.; it weighed 6·3 tons, and the weight in action was 14·8 tons. The carriage had hydro-pneumatic constant recoil gear, and gave elevation up to 65 degrees. This piece could be divided into loads easily transportable by road, the heaviest, 9·27 tons, being the howitzer itself on its special vehicle. It was very effective in its day, but a modern 11-in. howitzer would be expected to range at least 18,000 yd., and would probably be on a railway mounting.

*The 12-in. Howitzer.*—A number of pieces of this calibre were used on railway mountings by the different nations. The British 12-in. howitzer was used both on railway and on road mobile mountings. Of those transported by road, the most notable was the Austrian 12-in. howitzer (fig. 37). Several of these pieces were borrowed by the Germans to assist in the sieges of Belgium and northern France, and in Sept. 1914 they travelled 150 km. from Givet to the Moselle in a day. This howitzer fired an 858-lb. shell, M.V. 1,100 f.s., range 10,600 yd. The weight of the piece was only 5·9 tons, or lighter than the Krupp 11-in. howitzer, which was made extra heavy to reduce the recoil. The weight in action was 21¼ tons. This piece could only be fired from a platform. It was easily transportable by road. In addition to the borrowed Austrian pieces, the Germans had 305-mm. mortars of their own, the first pattern dating from 1898.

*The French 370-mm. (14·6-in.) Howitzer.*—This equipment, designed by Colonel Filloux, was brought out during the war. It is remarkable for its extreme simplicity and the ease with which it can be manufactured.

The howitzer is 8 cals. long, with plain interrupted screw breech-mechanism; it fires a 10-cwt. shell ranging 8,900 yd. or an 8-cwt. shell ranging 11,500 yd. It is mounted on trunnions in a small upper carriage or saddle, which slides on guides inclined at 6 degrees. The saddle rests on spring-supported rollers, so arranged that the springs give under the downward blow of discharge, allowing the saddle to come down on the guides. In checking the recoil, the friction of the guides is assisted by 2 plain hydraulic buffers. The lower carriage of which the slides form part is a single steel casting which traverses 12° on rollers on the platform. This is of steel, raised at the rear end, and has 4 rows of spades fixed to its lower surface; the whole platform is sunk in the ground, and the spades prevent it from moving. The howitzer is loaded "down-hill" from the raised end of the platform, by means of a small shell-trolley which runs on rails fixed in continuation of the saddle guides.

The equipment can be transported by road, rail, or narrow-gauge railway. Whichever is used, the 3 parts of the equipment (howitzer, carriage, and platform) are each suspended from an arched girder, called a "transporter." For road transport, the ends of this rest on two 4-wheeled road trucks, one following the other, which are drawn by a tractor. For ordinary rail transport, the transporter rests upon a single 20-ton truck, and for narrow-gauge transport the ends rest on 2 trucks.

For mounting and dismounting the howitzer the narrow-gauge railway is always used. A line is laid past the rear of the emplacement, parallel to the front. Two short lengths of rail are laid at right angles to the first line, connected to it by turntables. On arriving at these, the trucks carrying the ends of the transporter are each turned through a right angle, so that they can now move forward abreast, carrying the transporter between them. On reaching the emplacement, the platform is lowered from its transporter into the hole dug for it, and the process is repeated for the carriage and for the howitzer. The weights are: howitzer, 9·27 tons; carriage, 9·4 tons; platform, 9·9 tons; transporter, average, 2·5 tons. The transporter is 26 ft. long; the time required to mount the piece, not including laying the lines of rail, is under 2 hours.

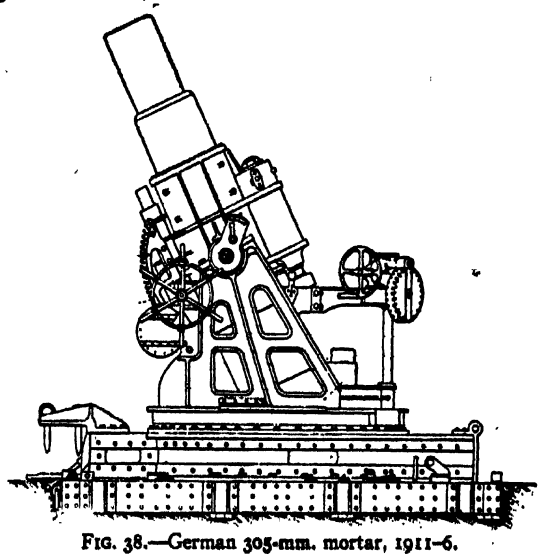

FIG. 38.—German 305-mm. mortar, 1911–6.

*Road-mobile Super-heavy Guns.*—In the World War few long guns above 8-in. calibre were provided with road-mobile mountings, and most if not all of these were old, short guns (say, 25 cals. in length) which at the present day must be regarded rather as long howitzers than as guns. Perhaps the heaviest serviceable gun on a road-mobile mounting is the Schneider 220-mm. of 1917 above described.

*The Austrian 38-cm. (15-in.) Howitzer.*—This weapon was brought out in 1916, and the Austrians achieved remarkable results in transporting it by road. The howitzer was 17 cals. long, and weighed 20·7 tons. The breech action was the Skoda wedge. It fired a shell weighing 1,320 lb., M.V. 1,530 f.s., ranging 16,700 yd. It had a ring cradle with the usual hydro-pneumatic recoil gear. The upper carriage, which weighed 16·6 tons, was fixed to a base plate which turned 360° on a central pivot and roller ring, which formed part of the top plate of a caisson platform. This was 22 ft. long, 17 ft. wide, and 4 ft. 6 in. deep, and weighed 43·4 tons empty before it was bolted together and filled with earth or concrete.

The interesting feature of this equipment was the means of transporting it. The howitzer was carried on a platform wagon mounted on 2 bogies of 2 axles, or 8 wheels in all. Each wheel was driven separately by an electric motor, the current being furnished by a 150-H.P. petrol engine driving a dynamo giving 90 K.W. at 300 volts. This engine and dynamo were carried by a power vehicle weighing 9·7 tons complete, which either preceded or followed the platform wagon. The latter weighed 15 tons, or 35·7 tons with the howitzer. The equipment consisted of 5 power vehicles and 5 platform wagons, carrying respectively the howitzer, upper carriage, sections of the platform, and 16 rounds of ammunition. The average gross weight was 35 tons.

Each of these 10 vehicles was fitted for transport by rail as well as by road. The wheels were composite, consisting of an inner railway

wheel and an outer broad-tired road wheel of larger diameter, namely, 42 in. When the vehicle was run on to the rails, the road wheels were taken off, and the power vehicle and the platform wagon then constituted a unit capable of travelling by rail under their own power. If it was desired to use a locomotive, the platform wagons could be coupled together to form a train, or could be embodied in an ordinary train. However, the power vehicle was not built stoutly enough to be coupled up as part of a train, and when a locomotive was used the power vehicle was carried on a truck.

To mount the howitzer a hole was dug for the caisson platform. The sections of the platform were dismounted from the wagons by screw-jacks and by winches worked from the power vehicle; they were bolted together in position, filled with earth or concrete, and the top plate, with roller ring and pivot, bolted down. A line of rails was then laid across the platform, and the wagon with the upper carriage was brought up on these rails. The ends of the wagon were jacked up, the bogies removed, and the upper carriage lowered through the bottom of the wagon on to its pivot. The howitzer was then lowered into its cradle in the same way.

*The Austrian 42-cm. (16·5-in.) Howitzer.*—This was designed as a coast-defence weapon in 1914, and must not be confused with the German weapons of the same calibre used in the Belgian sieges of 1914. In 1916 at least one of these Austrian pieces was equipped for transport by rail, and in 1917 a road-and-rail travelling equipment similar to that of the 15-in. howitzer was built for it.

The howitzer was 15 cals. long and weighed 25·9 tons with the breech mechanism. It was rifled with 84 grooves, uniform twist. It fired a shell weighing one ton, containing 198 lb. of H.E. in a brass cartridge case. There were 5 charges of from 64 to 120 lb., and the extreme range with the 20-cwt. shell, M.V. 1,380 f.s., was 14,100 yd. There was also a 16-cwt. shell ranging 16,200 yd. In 1918 the Austrians, who favoured heavy shrapnel, were designing a shrapnel for this howitzer, but it was never fired.

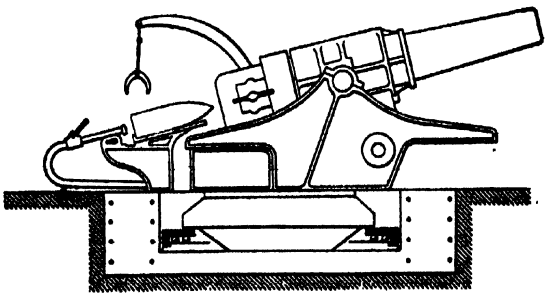

FIG. 39.—Austrian 42-cm. howitzer.

The mounting was of the same pattern as that of the 15-in. howitzer, but heavier. The upper carriage weighed 22·6 tons; there were 2 hydraulic buffers and 2 compressed-air recuperators, working at a pressure of 60 atmospheres. The howitzer could be fired only between 40° and 70° of elevation; thus the range was shortened by increasing the elevation. Fire at any elevation over 65° is unreliable, as the shell tends to come down base foremost or sideways.

The platform was built up of caissons, and measured 25 ft. by 21 ft. by 4 ft. 6 in. deep. It weighed 57 tons empty. The power vehicle and platform wagons were similar to those used with the 15-in., but the wagons weighed 18½ tons, and the heaviest load was 44 tons gross. This equipment was certainly transported by rail, but whether it ever travelled by road is uncertain.

*The Krupp 42-cm. (16·5-in.) Howitzer.*—A heavy pattern of this piece existed as early as 1911; the light or road-mobile pattern was a surprise brought out by the Germans at the beginning of the war, and intended especially to overpower quickly the resistance of permanent forts in a minimum of time.

The heavy 42-cm. howitzer was transported by rail. It fired several kinds of shell; the heaviest weighed 18 cwt. and contained 200 lb. of explosive; the lightest, which was fitted with a long false point, weighed only 8 cwt. and contained 110 lb. of explosive. The extreme range was 15,500 yd. The weight of the howitzer was 25 tons; it was transported by rail, but was not fired from a railway mounting. A portable platform had to be laid for it, and it was mounted by means of a gantry. With carriage and platform, the equipment formed 7 truck-loads of about 25 tons.

The light or road-mobile 42-cm. howitzer weighed about 21½ tons. It was 12 cals. long, rifled with 120 grooves, uniform twist, and had the Krupp wedge breech action. It threw a shell of 15·7 cwt., containing 302 lb. of explosive and ranging 10,300 yd. There was also an 8-cwt. shell as for the heavy 42-cm., which ranged 13,600 yd. This howitzer required 13 heavy steam traction engines to move it by road. The howitzer itself, on special wagon, was drawn by three traction engines, with a fourth in reserve for hills. The cradle formed a second load, and the empty carriage a third; the fourth and fifth loads were the platform, and the sixth was a wagon fitted with a heavy gyn and windlass for mounting the howitzer. This 42-cm. howitzer was fired from its wheels, and was the heaviest wheeled equipment ever built. It could not be fired from the bare ground; it used a portable platform under the wheels and a trail abutment. It was fired only between 40° and 60° of elevation. The carriage had a ring cradle with hydro-pneumatic recoil gear, giving 6 ft. of recoil, which was mounted on central trunnions on the lower carriage. The massive steel-disc wheels were provided with girdles. The platform was a steel casting in one piece, and extended under the wheels only. The trail abutment consisted of steel caissons or boxes, bolted together to form a curved caisson 7 ft. from front to rear, 10 ft. 6 in. wide, and 5 ft. deep. The caisson was shaped to form a step in front, which supported the point of the trail and formed an abutment behind it. This caisson was sunk into the ground behind the howitzer. A pinion on the point of the trail engaged with a rack on the abutment, and the piece was traversed by turning the pinion. The downward blow on firing was divided between the steel platform and the caisson under the trail. The caisson was made wide enough to allow about 60° of traverse.

The road-mobile 42-cm. howitzer fulfilled its strategic purpose well. The essence of the German plan of campaign was speed; they wanted a powerful siege howitzer which could be brought into action in the first few days of the war and which must therefore be independent of the railways in case these were found to be partly destroyed or otherwise unavailable. They therefore built a "super-heavy" short-range weapon just within the limits of weight for transportation by main roads, and capable of opening fire in a few hours without waiting for a permanent platform to be built.

It will be noted that the German 42-cm. howitzer is less powerful both as regards range and weight of shell than the Austrian 42-cm. already described, which piece also is claimed to be transportable by road, and it seems probable that the Austrian rather than the German pattern will be adopted in future construction.

*Railway Mountings.*—These are of great importance where the country is covered with a close network of railways. Irrespective of the great 100-mile guns, ordinary heavy guns on mobile railway mountings range about 18 m.; so that numerous positions are available for them within range of any desired target. Taking London as an instance, a circle with 18-m. radius drawn from Charing Cross passes through Redhill, Weybridge, Watford, Hatfield, Epping, Dartford, and Oxted, and crosses no less than 29 railway lines.

Railway mountings are of two main types: the all-round mounting, with which the gun can fire in any direction from its truck; and the curved siding, or gun-spur mounting. With the latter the gun is layed for direction by running the gun-truck along the curve till it points in the direction of the target. A variant of the second type is that in which the gun can fire from the truck only in the direction of the rails, while for all-round fire it is lowered on to a specially laid platform, and becomes a non-mobile gun.

The present tendency is to develop the all-round railway mounting. This has the advantage that the gun can be fired from any point on the railway; it can follow up the troops during mobile warfare or it can shift from day to day during non-mobile warfare, opening fire from fresh places. The curved-siding mounting takes time to prepare, and then ties the gun down to one position, unless alternative spurs are laid. It makes the fire slow, especially with mountings that run back along the track at every shot. Moreover, the curved siding and the track leading up to it are difficult to conceal. On this account the Germans, at the beginning of the war, used the permanent platform type, in spite of its immobility. They had no satisfactory all-round railway mountings, and, since they objected to the curved siding, they used to build a temporary line to a permanent gun-platform laid in a wood or other place suitable for concealment. Having mounted the gun, they took up the temporary line and removed all traces of it.

The main difficulty in designing a railway gun-mounting is to keep its height and width within the limits allowed by the railway loading gauge. The British loading gauge is 13 ft. 1 in. above rails in centre and 10 ft. 11 in. at sides; the width allowed is 8 ft. 6 in. on some lines and 9 ft. on others. The Continental loading gauge is approximately 14 ft. high and 10 ft. wide. Since the platform of the lowest commercial truck in use is 3 ft. 9 in. above the rails, this leaves little headroom available for a gun and mounting. There is practically no limit to the length permissible, as the girders constituting the mounting itself are carried on 2 or 4 bogies; nor to the weight, as railway bridges are quite strong enough to carry 15-in. gun-mountings. Neither is there any limit to the downward stress on the rails caused by firing, provided that it is taken by a sufficient number of wheels or a large enough bearing-area of platform. Some makers, however, require an extra set of rails laid, or even 2 extra sets (6 rails in all) for their heaviest mountings to fire from. These extra rails are especially necessary with those mountings in which the gun does not recoil on its carriage but the whole truck slides back along the rails on firing and has to be run up again after every shot; the recoil is absorbed by friction along the rails.

Experience shows that the track resists the downward pressure due to firing so long as this is within 3 kgm. per sq. cm., or 42 lb. per sq. in., on the ballast under the sleepers; that is, the resistance depends on the area of the sleepers. When the firing stress is locally high, owing to its being borne by some 12 baulks under the centre of the mounting instead of by 32 or more bogie wheels at the ends the

sleepers are laid at half the usual interval, and extra long sleepers are used. Sleepers laid in good ballast offer sufficient resistance to displacement by stress acting in the general direction of the line of rails, but, as was found in Flanders, a track laid in wet clay is liable to shift, and has to be anchored by driving in stout pickets.

Guns on British "rolling" mountings, as opposed to the French "sliding" types, are fired from the springs. That is, the downward firing stress, reduced by the hydraulic buffer, is taken on the ordinary truck springs. Messrs. Krupp, in their heavier mountings, jacked up the gun-mounting at every axle, so that the stress of firing came directly on the axle-boxes and not on the springs. Messrs. Schneider use wooden baulks under the central part of the mounting, which are jacked down before firing so as to bear on the 3 pairs of rails. In some American mountings the gun-mounting is jacked up and then lowered on to wooden baulks inserted between it and the rails.

FIG. 40.—French 155-mm. Schneider, on railway mounting.

On account of the limitations of height imposed by the loading gauge, all the heavier mountings have to be of the general type illustrated, namely, a pair of massive girders bent down in the centre nearly to rail level, with the ends supported on pairs of bogie trucks.

The lateral stability of a railway mounting supported on a line of rails of ordinary 4 ft. 8½ in. gauge is small, and it would be impossible to fire a heavy gun across the line of rails without some special support. Therefore all-round-fire mountings have lateral outriggers to take the firing stress. Modern improvements are in the direction of improving the efficiency of these outriggers.

All recent railway mountings allow of the gun being elevated to at least 40°, and to ensure room to recoil at high elevations rear-trunnions are usual, the resulting forward preponderance being balanced by counterweights or by compressed-air gear. Thus the German 11-in. gun had a box on the rear end of the cradle which was loaded with 4·5 tons of iron pigs. This box was dismounted for travelling, as it was too high to pass through tunnels. This was a clumsy device and entailed heavy labour in shifting the pigs. British and American makers use the hydro-pneumatic balance spring described earlier in this article.

In order to reduce the effort required to elevate heavy guns relieved trunnions are usually fitted to the cradle, or to the gun when no cradle is used. (This device is, of course, not peculiar to railway mountings.) The trunnions which support the piece when firing are necessarily of large diam. causing considerable friction. They are therefore fitted with projecting secondary trunnions of small diam., supported by rollers resting on leaf springs. These springs are adjustable by screws at their ends so that they take nearly the whole weight off the bearings of the main trunnions. This reduces the friction so that the piece can be easily elevated by hand gear.

In France there is an extensive network of metre-gauge railways built as feeders to the main lines, and these again connect with 60-cm. tramways. The latter were often joined up to the system of trench railways. In order to utilize this network of railways to the full, many French mountings are built with additional narrow-gauge bogies. These can be lowered and the main bogies raised so that the mounting can travel on its narrow-gauge wheels, but no attempt has ever been made to fire from them. They are used to convey the mounting to a prepared platform on to which it is lowered.

The heavier French, German and American railway mountings are provided with an electric power plant for running the gun-truck into position on the curved siding, hoisting the shell, ramming home, elevating, and closing the breech. The British mountings have usually power winches, run by small petrol engines.

Ammunition supply to a gun on railway mounting is by means of a trolley, running from the ammunition truck to the gun along a small tramway laid on top of the intervening trucks. For small calibres such as the 6-in. a long trough is used. The shell is hoisted by a crane and loaded by a power rammer; the gun is usually depressed to the horizontal position for loading. In all-round-fire equipments the loading platform traverses with the gun, so that the gun has not to be traversed to the fore-and-aft position after every shot.

In the French mountings which slide along the rails on recoil, the ammunition truck has to be uncoupled from the gun truck during firing. Ammunition has then to be brought up by a trolley running on a light railway laid by the side of the main track.

Roving railway guns were often used in Flanders. These were field guns or naval 12-pdr. mounted on trucks with all-round fire, and were run out by night to positions in the open whence they could enfilade German trenches and advanced works. They used to fire 50 rounds of rapid fire and withdraw before they could be located. But this was annoyance rather than serious warfare.

A heavy railway gun requires an attendant train, including ammunition trucks, workshop, trucks with materials and tools for building sidings and emplacements, and trollies (preferably motor-driven) for bringing up ammunition at night. The train is usually kept well back or camouflaged or both. But the real difficulty lies in concealing the specially laid sidings, and the places where they leave the main line.

*German Methods.*—The Germans used few if any railway mountings till 1916, although Messrs. Krupp had a 12-in. gun on truck mounting in 1913. They brought up heavy naval guns by rail and mounted them on permanent concrete platforms with central pivots; later they used steel caisson platforms bolted together on the spot and weighted with earth. The gun was brought up on a 40-ton commercial truck, or two such trucks for the heavier pieces. To mount it two temporary lines of rail were laid, one on each side of the platform and a third line up to the centre of the platform. A horizontal crane or gantry, consisting of a girder capable of carrying 40 to 100 tons according to the size of the gun, was supported at the ends on trucks run on to the two lines, so that the gantry was over the platform. The gun-truck was run up on the third line, the gun lifted, the truck removed, and the gun lowered on to its platform.

Later on, the Germans developed a new system which enabled the gun to be fired either from a railway mounting or from a platform. The railway mounting was of the ordinary type, consisting of two heavy girders bearing the gun-carriage, supported at their ends on trucks, and bent down in the centre so as nearly to touch the rails. The mounting was run on to a siding built across the platform, jacked up, the trucks removed, and the gun-mounting lowered on to the central pivot of the platform. The siding was then taken up and all traces of it were concealed.

In 1916 the Germans, impressed by the mobility of the French railway guns on the Somme, began to use travelling railway mountings more freely. However, they never developed a satisfactory traversing mounting, and their guns were nearly all on non-traversing rolling or sliding mountings layed by means of curved sidings. To save time in running the gun-truck forward after recoil, they used a scotch clamped to the rail, behind each wheel. By Nov. 1917 they had 9·45-in. guns of 30 and 40 cals., and 11-in. guns, long 9·45's, and, finally, 15-in. guns on truck mounts. In 1918 they had long 9·45-in. guns of 45 cals., and by July 1918 they had 15-in. guns on truck mounts.

A representative of the lighter nature of railway guns designed for all-round fire is the Schneider 155-mm. (6·1-in.) gun shown in fig. 40. This was a 28-cal. siege gun of only moderate power, but it proved very useful in the early days of the war. The railway mounting is of simple construction. The gun recoils up inclined guides and returns to the firing position by its own weight. The carriage is on a roller ring fixed to the platform of the truck, and gives all-round fire. The truck is supported when firing by screwing down the baulks underneath it upon the rails; the outriggers seen in the plate are used when firing across the rails. This gun fires from the ordinary permanent way, no extra rails are required, and only a few minutes are spent in coming into action. Another example is the French 19-cm.

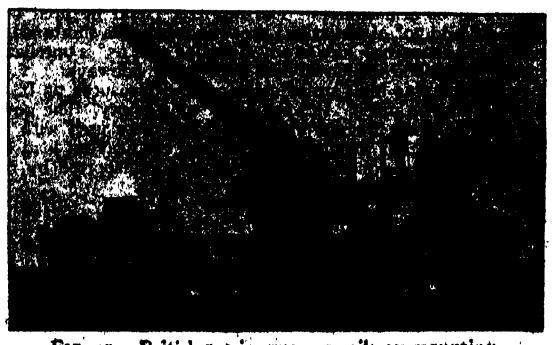

FIG. 41.—British 9·2-in. gun, on railway mounting.

*The British 9·2-in. Gun on Railway Mounting.*—The 9·2-in. gun formed the principal armament of the British coast defences. In 1914 a number of old guns of this calibre were sent to France, and these were afterwards replaced by Mark X. guns from coast defences, and later by Marks XIII. and XIV., which were more accurate at long ranges. The gun weighs 30 tons and fires a 380-lb.,

shell ranging 26,000 yd. at 40° elevation. The weight with mounting is 92 tons. The Armstrong railway mounting for this gun is shown in fig. 41. The gun has no cradle; to adapt it for the railway mounting a trunnion ring is shrunk on and a balance weight added to the breech. It is mounted on a small upper carriage, recoiling on the main carriage; the recoil is checked by a hydraulic buffer, and the upper carriage returned to the firing position by springs.

The main carriage traverses on a roller ring on the upper surface of the platform girder which is of the usual type, supported at each end on a pivot carried by a six-wheeled bogie truck, the centre pair of wheels being flangeless.

Four outriggers, which are shown in the raised position in the plate, are pivoted to the sides of the main girder. Before firing, the main girder, with the gun and carriage, is lowered by means of hydraulic jacks which are embodied in the pivots which support the ends of it, so that it rests upon the sleepers of the permanent way. The outriggers are swung out, stayed, and bedded in the ground, and the gun is ready to fire. The operation takes half an hour.

This mounting requires no preparation of the permanent way; the gun can be fired from any point in the open line, at the rate of about one round in 50 seconds. The outrigger system would require modification to admit of heavier guns than the 9·2-in. being fired from it; even with this gun reduced charges have to be used when firing across the rails at angles of elevation below 15 degrees.

It should be noted that all outrigger mountings block both lines of rail when in position, so that no traffic can pass. This is one argument in favour of the curved-siding system.

The largest all-round railway mounting used in the war was a St. Chamond mounting, originally made for a 12-in. gun, but as this proved too violent, actually issued for service with the 240-mm. "Colonies" coast-defence gun. The gun is 40 cals. long, with trunnions, and fires a shell of 356 lb., M.V. 2,800 f.s. The mounting consists of an upper carriage recoiling against gravity and a buffer.

FIG. 42.—British 12-in. howitzer, on railway mounting.

The slide is pivoted on the main girder and traverses through a complete circle; it is extended to the rear to form a loading platform. The track requires preparation in the form of extra sleepers, to which are bolted 4 longitudinal baulks, these forming the bed to which the main girder is firmly secured. The horizontal stress due to the recoil is taken by long outriggers, 2 on each side and 2 at each end, which abut on massive shoes buried in the ground.

The British 12-in. howitzer on railway mounting is shown in fig. 42. The howitzer is 18·6 cals. long, weighs 10½ tons, and throws a 750-lb. shell about 16,000 yd. The mounting is very similar to that of the 9·2-in. gun, but has a cradle with hydro-pneumatic recoil gear. In this plate the outriggers are seen bedded in the ground.

*The 274-mm. (10·5-in.) French Gun.*—This gun is shown in fig. 43 on a Schneider sliding railway mounting. This is a good specimen of the French mountings designed early in the war. The French had a number of coast-defence guns with trunnions, mounted on slides, with no cradles or hydraulic buffers. It would have taken a long time to make hydro-pneumatic recoil gear for these guns, and the Schneider sliding mounting enabled them to be used at once. The gun fires a 561-lb. shell, M.V. 2,717 f.s., and ranges 29,000 yd. It is mounted on its trunnions on a girder supported at both ends by trucks. The mounting gives 45° elevation, and no traverse; the gun is layed for direction by shifting the whole mounting along a curved siding. For this purpose a winch actuating the two leading axles is fitted on the front truck. The gun weighs 38·4 tons, and the whole mounting with the gun weighs 152 tons. The curved siding is specially laid for firing. The sleepers are extra long, and are at half the usual distance apart. Four extra rails or I-shaped girders are laid. The siding is built to a radius of 180 metres;[1] if the mounting is shifted approximately 100 metres along the siding, this gives a change of direction of 60 degrees. Under the main girder is a set of heavy transverse baulks (the ends of which can be seen in the illustration). Before firing these are jacked down on to the rails so that the weight of the system rests on the rails and the truck springs are eased. On firing, the whole truck mounting slides back along the rails for about 2 metres. Its motion is checked by the transverse baulks.

This type of mounting has the advantage of ease and simplicity of manufacture; it can be made in any engineering works, and there is no complicated hydro-pneumatic recoil gear, which requires special tools and experienced workmen to make. The siding is an ordinary piece of railway construction. Once it is built, no special preparation for coming into action is required, and the gun can take up its position and open fire within one hour. Tactically this mounting is inferior to one which allows firing from the open line.

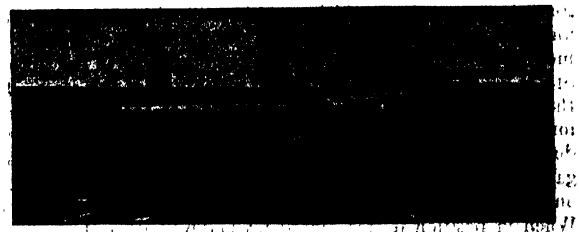

FIG. 43.—French 274-mm. gun, on Schneider sliding railway mounting.

*The 30·5-cm. (12-in.) French Gun on Batignolles Railway Mounting.*—This mounting is of a type intermediate between the all round and the curved siding mounting. The gun recoils in a cradle, with hydro-pneumatic gear; the characteristic feature is that it traverses 5° each way on the mounting. A special platform is laid for it, consisting of a framework of which the transverse members (with spades on their under-sides) rest on and bite into the ballast between sleepers, and the longitudinals come under the main girders of the carriage. The mounting being run over the platform, wooden wedges are then driven between the beams and the bottom of the girders, so that the mounting is firmly supported on the platform. Recesses are formed in the lower edges of the mounting and the upper edges of the platform, to prevent the wedges from shifting. The platform provides a base nearly 10 ft. wide, this being the limiting width of the main girders of the mounting, imposed by the railway loading gauge.

The platform does not, it is stated, interfere with ordinary traffic when laid. It is therefore possible to provide several platforms on the open line for the same gun, provided that places can be found where the line points within 5° of the target.

Where a definite target is to be engaged, and where consequently only a small amount of traverse is required, the Batignolles mounting has great advantages over the type requiring a curved siding, which takes a week or more to build.

When worn, the gun is bored out to 370 mm., mounted on almost the same way as before and used as a howitzer.

FIG. 44.—British 14-in. gun, on Armstrong rolling mounting.

*The French Schneider 520-mm. (20½-in.) Howitzer.*—This fired the heaviest shell used in the war, weighing 2 ton 6 cwt. The muzzle velocity is only 1,640 f.s., and the range 26,000 yd. Unlike the French heavy guns, this piece was specially made as a railway gun. The mounting is of the Schneider sliding type above described, but the gun has a ring cradle and hydro-pneumatic recoil gear, for without this the downward blow on firing would have been too severe on the mounting and the rails. It has electric gear and the breech block is worked by a cylinder containing air which is compressed by the recoil. The howitzer weighs 44 tons and the mounting with howitzer weighs 265 tons.

*The British 14-in. Gun.*—This gun fires a 1,400-lb. shell ranging 35,000 yd. Fig. 44 shows it on an Armstrong rolling mounting. The whole mounting rolls back along the rails on firing, and is hauled

[1] For heavier calibres, Schneider lays down 150 m. as the radius.

forward again by two power winches and tackles attached to hold-fasts beside the line. The gun recoils in a cradle with ordinary hydro-pneumatic gear; the upper carriage traverses 2° each way. Traverse beyond this limit is given by a curved siding.

This gun has rear trunnions and the hydro-pneumatic balance-spring already described. The advantage of the mounting is that the gun can be fired from the ordinary permanent way without any preparation; no extra rails are required, there is no platform, and the downward stress of recoil is taken on the truck-springs without the necessity for jacking them up. (H. A. B.)

### (VI.) Railway Pivot and Fixed Mountings

German designers during the war showed a marked preference for railway mountings which could be utilized both on the rails and in a prepared emplacement. Since the war, the development of mountings of this class has been taken up in the United States. The British did not favour mountings of this class. In the French service the pioneer mounting of the rail-and-platform type was a 240-mm. equipment on Tournier carriage with double recoil gear. In this the truck, on arrival by normal-gauge railway, received under its ends two light railway bogies, on which it was brought to a prepared firing platform with pivot. When in position it was jacked up bodily, with ordinary and light-railway wheels still attached and lowered over the pivot. The gun travelled separately and was mounted after the carriage had been got into position. A much more powerful mounting, which, though it gave only a limited traverse, must be regarded as a true pivot-mounting, was the 45-cal. 340-mm. (13½-in.) gun mounted on St. Chamond truck. This, like the preceding, was fired only from a prepared platform, but it travelled complete and the platform was prepared (for a traverse of 10°) on the railway track itself. It will be seen from the illustration that the travelling truck was brought over a pivot prepared in the line and jacked up. The long bogies were run clear and the main girder then rested in its centre on the pivot and at its ends, by jacks, on two platforms prepared in the line. The rear platform was connected with the pivot seating by girders, and the rails between them were removed and a recoil pit dug. The weight of the equipment (bogies included) was 166 tons, and the range of elevation from 15° to 42°. Unlike these, the German and American mountings now to be described were all capable of being used as indifferently rolling (or sliding) mountings and as immobile pivot-equipments.

*German Railway Mountings.*—The railway mounting of the German 11-in. gun was a good specimen of the German pattern intended to fire either from the truck or from a platform. The gun was a 40-cal. naval gun weighing 45 tons; it threw a shell weighing 630 lb., M.V. 2,740 f.s., to a range of 30,800 yd. It is possible that a streamline shell with supercharge, ranging about 35,000 yd., was also used. The gun had ordinary recoil gear, with an air recuperator working at 85 atmospheres, allowing 38 in. recoil. It had rear trunnions and counterweight as already described. The mounting had electric power gear throughout, enabling a rate of fire of 2 rounds a minute to be attained, at any rate, with platform mounting.

In the railway mounting, the weight was taken by jacking up the springs so that the axle boxes (20 in all) transmitted the strain to the rails, and recoil so far as not absorbed by the buffer and recuperator, was taken up by scotches behind each wheel. A total traverse of 2½° could be given.

The platform gave an arc of fire of 180 degrees. It consisted of 2 transverse caissons, 24 ft. long, on which were laid 3 longitudinal caissons 30 ft. long. These were laid, bolted together, and filled with 45 tons of earth. The central longitudinal caisson carried the steel top plate of the platform with roller ring; and the main girder of the railway mounting, with the gun, was lowered on to the pivot, and traversed on rollers which travelled round the roller ring. The platform was laid, and the gun mounted on it, by means of 3 temporary lines of rail and a gantry, as described above, or by means of screw-jacks by which it could be raised to remove the bogie trucks, and then lowered on to the roller ring. In the later equipments auxiliary machinery was fitted, driven by the electric power plant used in working the gun. The work of laying the platform, not including the temporary railway, took from 4 to 7 days, and the gun could be mounted in one day.

*The German 380-mm. (15-in.) Gun* was used in the field in 3 ways—as a railway gun pure and simple, as a railway gun with fixed pivot, and as an immobile gun in a semi-permanent emplacement. The gun itself was a 15-in. naval gun 45 cals. long and weighed 77½ tons. It threw a comparatively light false-cap shell weighing 785 lb. with a bursting charge of 69 lb., and 3 driving bands, the design of the projectile being generally similar to that of the 75-mile gun which bombarded Paris (see below). In this case the maximum range was 28 miles. The gun had a ring cradle with buffers and recuperator admitting of a 50-in. recoil. It had a counterweight over the rear of the ring cradle to lighten the work of elevating.

As a railway gun it was mounted on a truck of the usual type, but an intermediate carriage between the cradle and the girders enabled 1° of traverse to be given either way. The position of the trunnions was such that in firing from the open track no more than 17° elevation was possible, representing a range of less than 27,000 yd.—only one-half of the range which could be obtained with the gun emplaced. In the firing position, the weight was taken and the shock not absorbed by the cradle transmitted by the axle boxes of the bogies, as in the 11-in. mounting above described. The total of axles in this case was 18. The gun was layed for direction by movement along a curved siding of 180-in. radius. The total weight was 270 tons. This was the largest railway mounting used in the war.

When the railway mounting was used with an emplacement, the latter was provided by a number of caissons 7 ft. deep, bolted together so as to form a ring 40 ft. in diam., leaving a central pit recoil. The caissons were laid on a foundation of 3½-in. iron plates resting on I-girders. On top of the caissons was the platform plate, with a roller ring about 36 ft. in diam.; the main girder of the railway mounting was supported by rollers on this ring. The gun was let down to the platform by jacks permanently fixed in the main girder, and no gantry was required. This mounting allowed of 55° elevation; the range was 52,000 yd., and the rate of fire was one round in 3 minutes. The total weight of the gun and platform, besides the concrete filling of the caissons, was 270 tons. The platform took 3 weeks to build, not including the line of rails leading to it. Under favourable circumstances the gun could be mounted in one day.

FIG. 43.—German 380-mm. gun, on railway mounting.

The fixed mounting was of a type peculiar to this equipment known as the "bridge mount." It can be used only with a gun which, like this one, has a low recoil-energy due to the abnormally light weight of the shell compared to the gun. The bridge mounting consisted of a quadrant-shaped pit spanned by a bridge formed by a pair of massive girders between which the gun was mounted on its cradle trunnions. The bridge was pivoted at the front end, and the rear end traversed on rollers round the quadrant arc at the back of the pit, giving a total traverse of 90 degrees. The cradle trunnions were 1 ft. 6 in. in diam. and rested in trunnion bearings on top of the girders, 11 ft. 6 in. from the front ends. The girders were 35 ft. long, 6 ft. 6 in. deep, and 6 ft. apart. The pivot at the front of the bridge was 7 ft. in diam. and 6 ft. 3 in. high, carried by a cast-steel base bolted down with 3-in. bolts to a steel platform 20 ft. square. The sides of the square were formed by steel box girders 4 ft. broad and 6 ft. deep, produced towards the back of the pit. This was formed by a quadrant-shaped steel caisson to which the ends of the box girders were bolted; the caisson was 3 ft. 6 in. from front to rear and 7 ft. deep. It carried the roller quadrant, 32 ft. in radius, along which the rollers supporting the rear end of the bridge rolled. The pit was 10 ft. deep. The gun was mounted by means of a gantry carried by 2 trucks on 2 temporary lines of rail, one on either side of the pit.

*The German 75-mile Gun (called "Big Bertha").*—In March 1918 the Germans bombarded Paris from a distance of 75 m. The tactical aspect of the question of fire at this and at longer ranges is discussed under Artillery, this article being concerned with the gun itself. The 100-m. gun, so called, was not a new invention; designs for similar weapons had been prepared by the British and French Governments some years before the war, but had not been carried out, as the advantages were not considered sufficient to warrant the expense. A design, due to Col. Maitland-Addison, is shown.

The principle on which the gun depends is that if a shell be fired so as to pass through the dense layer of air next to the earth's surface and to emerge into the very thin atmosphere which exists at a height of 10 m., its flight will be practically unimpeded until it descends again, and therefore its range will be very considerably increased. The German shell in question rose to a height of 24 m. during its flight, and more than 50 m. of its trajectory lay in air of a density less than one-tenth of that at the earth's surface. To obtain this result the shell must be fired at an angle of 55° to the horizontal, and

with a high velocity, so as to get through the layer of dense air as quickly as possible. In this case the velocity was about 5,000 f.s., or a mile a second.

The gun was made by boring out a 15-in. naval gun, 56 f.t. long. An inner tube 98·3 ft. long was inserted into the gun, so that 42·3 ft. of it projected from the muzzle, and this projecting portion was covered by a "hoop" or outer layer of steel locked to the muzzle of the original gun. Further, a smooth-bore section of tube, 19·7 ft. long, was attached to the muzzle. This was put on with a screw collar, like the muzzle of the British mountain gun, and was removed for transport. The inner tube was of 21 cm. (8·27 in.) cal., and was thick enough to be bored out to 24 cm. (9·45 in.) and again to 26 cm. (10·24 in.) as it became worn. It was rifled with 64 grooves, uniform twist. The powder-pressure was 19·64 tons per sq. in., which is rather higher than that allowed in ordinary heavy guns. The original breech mechanism was retained. The total weight was 142 tons.

The shell used with the gun, at its original 21-cm. cal., weighed 264 lb. It had to be light to obtain the high velocity required.

The object of the smooth-bore section at the muzzle is not very clear; this feature is not embodied in the guns of this type built or designed by other nations. The object of lengthening the muzzle was to increase the range; the object of making the muzzle section detachable was to facilitate the transport; and the object of making this section smooth-bored instead of rifled may have been either to reduce friction or to steady the shell after leaving the rifled portion. Being smooth it would naturally wear less than if rifled and would maintain the accuracy of the gun longer.

The recoil mechanism of 2 hydraulic cylinders and one spring pneumatic recuperator cylinder was attached to the bottom of the cradle. To the top of the cradle was attached a counterweight, the 2 sections of which were raised and locked together for the purpose of raising the centre of gravity to such an extent that the gun might be elevated and depressed more easily. The cradle was on central trunnions, so that the gun was balanced without forward preponderance. A pit in the ground about 18 ft. deep gave room for recoil.

The elevating mechanism was extremely heavy and unique in design as screw mechanism was not used. Straight racks moved in ways parallel to the inclined lower face of the forward end of the side girders of the mounting; at the lower end they were connected with each other by a heavy shaft to which were attached 2 connecting rods running up to the bottom of the cradle. A 2-speed transmission was provided permitting operation at high or low speed.

The railway carriage body was made up of 2 single web-girders connected at front and rear by heavy structural steel transoms, and reënforced in front by a heavy cast-steel housing for the elevating gear. Owing to the great weight of the 75-mile gun compared to that of its shell the recoil energy was very low, and was considerably less than that of the 15-in. gun.

The dimensions of the gun (without muzzle section) and of the truck were not such as to present any special difficulty in movement by rail. The arrangement for bolting the carriage to the emplacement was in 2 main sections, one a base and the other a rotating section. Each section was built up of steel girders and plates. The rotating section was supported on steel balls. At right angles to the direction of the track of the rotating section were 2 girders on the ends of which were key-plates.

The mounting was run on to the emplacement with the rotating section in position and then raised by 4 jacks.

When raised, the bogie-trucks were removed and the rotating section of the emplacement turned through 90 degrees. On lowering the mounting, key-plates fixed under the carriage were fastened to corresponding key-plates on the emplacement. A circular traversing rack of angle and steel pins was bolted to the structural base.

The supposed position of the 75-mile gun was bombarded by the Allies, but it was never hit nor even exactly located.

The guns wore out quickly, owing to the large powder charge employed, and the accuracy soon fell off. The first 21 rounds fired at Paris on March 23 1918 showed that the 50% length zone was about 2 m. and the 50% breadth zone about ¼ m. The fall of the 21 shells fired next day showed an increasing dispersion, and the 6 shells fired on the following day were still more erratic. The gun then stopped firing, and, as was afterwards ascertained, was found to be worn out, and was sent home to be re-bored. Four days later a second gun had been mounted, and the bombardment began again, with similar results as regards accuracy. Altogether the Germans used 7 of these guns, and by Aug. 9, when the Allied advance obliged the Germans to withdraw, all 7 had been re-bored to 24 cm. After the Armistice it was learned that these guns were at Krupps, being re-bored a second time to 26 cm. The 3 guns building at Skoda for the Germans were never finished.

At the end of the war, the British, French and Italian Governments were each building at least one gun of this type. Few details of them have been published. The Italian gun is of 7·87 in. calibre, 65·6 ft. long. It fires a shell of 231 lb. with M.V. 4,920 f.s., and ranges 87 m. The greatest height of the trajectory is 25 m. It is stated that the British and French guns are of rather larger calibre, and range further. Both are said to be 104 ft. long, and to be rifled throughout, with no smooth-bore section at the muzzle.

The 100-mile gun is relatively an inaccurate weapon, owing to the variable atmospheric conditions which the shell may encounter during its flight, which was about 3 min. for the German gun. Improvement in this respect is not probable unless it be possible to obtain meteorological reports from high-flying aeroplanes at both ends of the trajectory, or unless a gun of far greater power, firing a shell of at least half a ton, be used. Such a degree of inaccuracy renders the 100-mile gun, as used in the war, nearly useless at any target smaller than a city, and a few shells distributed over such a large area can do little material damage, and can only serve the purpose of annoying or intimidating the civilian population.

*American Railway Mountings.*—The United States had 144 heavy guns on railway mountings in France, including five 14-in. guns. The latter were on sliding mountings of the French type but had central trunnions and no balance springs, and consequently could not be elevated beyond 15 degrees. The U.S. 16-in. howitzer was on a rolling mounting which allowed 5° of traverse each way, but it could not be fired with full traverse at elevations under 40 degrees. Since the war, the United States has been considering the question of substituting mobile railway guns for fixed guns in its coast defences. Such guns require a large arc of fire, usually 180°, and a high rate of fire, namely, at least one round a minute; consequently curved-siding mountings would not answer the purpose. It is therefore desired to develop the all-round-fire type of mounting so as to take as heavy a gun as possible, and to open fire as quickly as possible. Guns which are too violent for an all-round truck mounting, such as the 12-in. and over, will have to be let down on to a platform to fire. As it would be difficult to provide permanent platforms in every place where they might be required along the seaboard of the United States, the endeavour is to design temporary platforms which can be laid when required with the least possible delay.

*The U.S.A. 12-in. Howitzer on Railway Mounting.*—This howitzer is 20 cals. long and ranges 22,000 yd. with 700-lb. shell. It is on an all-round-fire mounting with 8 outriggers. Instead of being lowered on to the sleepers as in the Armstrong pattern, it is jacked up high enough to insert 6 wooden baulks between the main girder and the rails which are doubled by I-beams, and then let down on to them. The howitzer recoils in a cradle and traverses 360° on a roller ring. This mounting can be used for howitzers up to 12-in. and guns up to the 8-in. inclusive, but not larger, as the size of the roller ring is limited by the loading gauge.

FIG. 46.—U.S. 14-in. gun, on railway mounting. Travelling position.

*The U.S.A. 14-in. Gun on Railway and Platform Mounting.*—This gun ranges 22 m. at 50° elevation with 1,560-lb. armour-piercing shell, or 29½ m. with streamline shell. It is mounted in a cradle with the usual hydro-pneumatic recoil gear; the cradle is on central trunnions so as to balance the gun, and the breech projects so far to the rear that the gun cannot be elevated beyond 15° when fired from the railway. The main girder and bogie trucks are of the ordinary type, allowing a traverse of 2° each way.

This gun is fired from a curved siding, and the mounting then slides back at each shot and has to be hauled forward again. When either the full range or a large arc of fire is required, the main girder, with the gun, is let down on to a platform. This is of simple design, and consists merely of a circular platform plate laid on the ground and held in position by about 60 steel stakes 18 in. long which are driven round it. The platform plate weighs 34 tons; it is in 2 pieces, bolted together on the spot, and it constitutes the pivot plate and roller ring. The steel stakes take the horizontal thrust of the recoil. The centre of the main girder of the railway mounting rests on the roller ring; the rear end is supported by screw jacks embodied in it, which rest upon circular steel castings laid on the ground. These have to be shifted when the mounting is traversed. It is stated that on sound level ground this platform can be laid in 8 hours, and the gun can be lowered on to it in one hour.

The 1920-pattern mounting for the 14-in. gun is an improvement on the model just described. It has a top carriage pivoted on the main girder, giving 3½° of traverse each way. To prepare the gun for firing, the mounting is jacked up and lowered on to cross baulks as in the 12-in. howitzer mounting. Outriggers are provided in rear to take the horizontal thrust and the mounting is not allowed to slide back on the rails. The steel platform for all-round fire differs from the earlier pattern in that it has a roller path upon which the rollers

supporting the rear end of the main girder travel; this is an improvement on the method of supporting it with jacks and circular castings (see fig. 47). This gap has a complete electric power plant, furnished by a 25-K.W. petrol engine and dynamo. The same mounting is used for the 16-in. 25-cal. howitzer.

The simple steel platform used with the American 14-in. gun is in marked contrast to the elaborate platform, consisting of a ring of caissons sunk in the earth, used by the Germans for their 15-in. gun. It is stated that the American platform answers its purpose well. It remains stable, and, even if it does not maintain its level accurately, the resulting error is eliminated by the reciprocating sight. If it be possible to lay a platform for a super-heavy gun in 8 hours, instead of the 3 weeks required for the German pattern, and to mount the gun on it in one hour instead of 24, then this enables the gun to open fire from any desired point on the railway, or close to it, quickly enough for all practical purposes of land warfare, though hardly quickly enough for emergencies that might arise in coast defence. So far as land warfare is concerned, it would seem that the introduction of an 8-hour platform will render it superfluous to build all-round railway mountings for anything heavier than the 11-in. or 280-mm. guns. For even if it were possible to produce an all-round-fire railway mounting for a 14-in. gun, such that it could fire from any point on the open line without a platform, it would probably take 2 hours to fix and bed the outriggers, and the gain in time would hardly compensate for the increased cost and complication of the mounting as compared to the simple American type.

In the design for fixed mountings proper—that is, mountings and emplacements deliberately prepared in peace-time with the aid of concrete and armour—the conditions of the World War brought about little change. The types described and illustrated at 20.226 are still maintained in principle, improvements having been made in details only. A very general review, therefore, will suffice here.

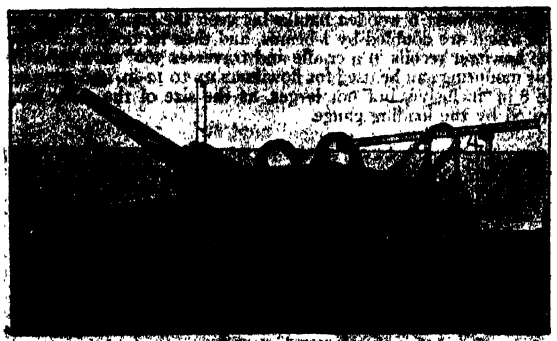

FIG. 47.—U.S. 14-in. gun, on railway mounting. Firing position.

Disappearing mountings are now no longer made, though some remain in service in America. These give the best possible protection against hostile fire, but naturally involve a very complicated mounting; and further, should the lowering and raising arrangements go out of order, the gun is rendered useless. High-angle mountings are still utilized in some places, mounted in deep pits for protection. They are largely used by the United States.

The utility or otherwise of cupola mountings in land fortifications is a question which the experience of the World War has made more controversial than ever. The answer lies, however, in tactical, not technical, considerations.

Coast-defence guns in permanent emplacements are now usually mounted on pedestals *en barbette*, as shown in figs. 84–87 at 20.229, 230. These mountings give all-round fire with breastwork protection as high as the gun level and armour in the form of a thick gun-shield above that level. All barbette pedestal mountings are generally similar in design. The emplacement is prepared by embedding anchoring plates in the concrete foundation and to these a cored pedestal is bolted down. Arrangements are made for levelling the pedestal as required. The pedestal supports the superstructure consisting in intermediate carriage, cradle, gun and gears. The intermediate carriage is capable of revolution in a horizontal plane about the centre of the pedestal and means are usually fitted to prevent it lifting on firing. Fixed to the pedestal is a graduated arc, correctly oriented, and to the intermediate carriage a pointer to indicate the training or traverse of the gun. The cradle carries the gun and recoil system, and is supported by trunnions on the intermediate carriage; the gun and cradle are elevated about the trunnion axis by elevating gear, whilst both the elevating system and the sights—the latter usually being fitted to each side of the mounting—are provided with scales to indicate the corresponding range.

With medium and heavy guns a platform is suspended on the intermediate carriage for convenience in loading and laying. All are provided with shields which cover the upper portion of the mounting and traverse with it. The intermediate carriage fits in or on the pedestal, and to lessen the friction consequent on traversing various devices are employed.

With light mountings, the lower portion of the intermediate carriage is formed with a stem projecting downwards into the pedestal; hardened steel studs let into the bottom of the stem and the recess in the pedestal support the whole weight of the superstructure. With medium mountings, the intermediate carriage is supported on a ring of hardened steel balls carried in a recess at the top of a pivot fixed into the pedestal.

The intermediate carriage of a heavy mounting is supported on a live roller ring; the rollers take the load on their circumference, not on their axles, and can move independently of the mounting. The rollers are kept equidistant by being mounted on axles between concentric rings, and are arranged to run between upper and lower roller paths; they are coned to give circular rolling motion without skidding, and are flanged to fit over the roller paths. The intermediate carriage is centred and steadied by a pivot fixed to the centre of the pedestal. The hardened studs give a form of point contact, the ball race gives circular line contact, and the roller ring circular ring contact. Thus the area in contact is kept at a minimum consistent with the weight of the superstructure for the mounting to be traversed with the greatest possible ease.

So far as circumstances permit, the same principles of support are employed in the semi-fixed and railway-pivot mountings dealt with above. How far improvements in railway-pivot mountings will enable guns fired from them to rival the accuracy of guns fired from the fixed and bedded mountings hitherto used in coast defence is an open question. All mountings (except the lightest which can be easily moved by hand) are provided with traversing gear.

Prior to the World War fixed mountings were designed to permit of a maximum elevation of about 20°; but they are now being designed to give elevation up to about 40 degrees. This necessitates a taller intermediate carriage and longer arcs on the cradle. To reduce the work of elevating the heavier guns the trunnions are mounted in ball or roller bearings. With ball-bearings, which give a point contact, the bearings are supported on springs to support the trunnions only when elevating; on firing, the spring supports give and allow the trunnions to bear upon the intermediate carriage, thus relieving the balls from the firing stresses. In the design of elevating (and also traversing) gear provision is made for relieving the mechanism of shock strains.

The ring type of cradle, being suitable for short recoil, is in general use. The recoil system is usually carried underneath the cradle and consists in a buffer of the valve-key type and springs or compressed air for recuperation. Springs are now being superseded except for light mountings, and the pneumatic recuperator is coming into general use with the increased elevations for which mountings are being designed. With very heavy guns a slipper is employed to support the gun in the cradle, recoil with it, and connect with the recoil system. Hand-loading obtains with light and medium guns, but with heavy guns machinery is employed with hand-gear as a standby in case of breakdown. (X.)

## (VII.) Naval Ordnance and Gunnery

The many lessons learnt from the World War as to the results obtainable by naval artillery, and the multitude of improvements in material and in the methods of using it, were in 1921 still in process of digestion by the leading naval Powers. In so far as they reflected upon the design of future warships, from the point of view of naval ordnance, these lessons were still kept as closely guarded secrets in official quarters. The chief factors can, however, be stated in general terms.

The outstanding factor is the long range at which the naval actions of the war were fought by all types of ships. This was due primarily to the great destructive power of modern shells, and partly also to the increased range of the torpedo. It is true for all types of ships, from the capital ship to the destroyer and submarine. In each type the tendency has been to increase the size of the gun armament and to demonstrate the paramount importance of carrying guns of the largest possible calibre. This general increase in the size of the guns has been common to all navies. The British navy will, however, be taken here as typical of the changes that had already taken place before 1921 and of the further developments in progress.

Before the war, 10,000 to 12,000 yd. was considered to be the probable fighting range between squadrons of heavy ships, and it was not thought likely that these ranges would be greatly exceeded. It had now been proved that 12,000 yd. was about the minimum range at which any heavy ship action had been fought during the war, while the maximum range extended to 20,000 yd. and even beyond that. This range approaches the limits of vision at sea, except under abnormal conditions of visibility. If we take into account the use of aircraft for observing, there appears to be no likelihood of the range being reduced

in the future. In fact, it seems not improbable that future naval actions will be fought between fleets at extreme ranges and out of sight of one another, either on account of smoke screens or of the prevailing limit of visibility on the surface. This will produce an entirely new set of conditions, both from the point of view of the effects of gunfire and of the methods by which the guns are used.

Let us consider first the effects of gunfire. At extreme ranges the angle of descent of the projectile is very steep, and the target presented by the vertical armour of a ship becomes small in proportion to that offered by the thinner horizontal armour. Again, the large angle of descent means that the vertical armour will be hit at a considerable angle to the normal and is therefore more difficult to pierce. An excessively thick belt of side armour, therefore, tends to become so much deadweight. In the long race for supremacy between gun and armour, the gun had forged a long way ahead when the attack was made so that the projectile would hit at right angles or normal to the surface of the plate. Modern armour-piercing shells are now capable of piercing the heaviest armour carried afloat, even when fired at long range and striking at moderate angles to the normal. Moreover, these shells can carry their bursting charge of H.E. through the armour in a condition to explode and so do the desired damage to the vitals of the enemy. Moderately thick horizontal armour is, however, capable of keeping out the heaviest projectile, even at the steep angles of descent which occur at very long ranges, since the angle to the normal at which the armour is hit is very much increased when the plates are presented horizontally to the line of fire. It therefore appears certain that a considerable increase in the horizontal protection must be one of the features of the designs of future warships, with a corresponding decrease in the area covered by the thick vertical armour. Again, the development of attacks upon ships by aircraft with bombs must lead to a desire for increased horizontal protection. The great destructive effect of H.E. points to the necessity of a more extensive subdivision of the ships internally, in order to localize the effects of shell bursts; and protection against torpedoes will have the same tendency.

The problems with which the control officers are faced become much more complicated as the range is increased. At ranges that approach the limits of visibility, the observation of the fall of the shot becomes very difficult, and it is practically impossible to decide whether the shot are falling over or short, unless they are directly in line with the target. As the range increases, errors caused by the roll, yaw and pitch of the ship, which are not so serious at moderate ranges, become accentuated, and have to be taken into account. The trajectory reaches a very high altitude, and the conditions of wind in the upper atmosphere cannot be known with sufficient accuracy to enable a correct forecast to be made of the effect on the projectiles. The effects of the variations in muzzle velocity of the guns, due to the wear of the guns, changes in the temperature of the charges, and other more obscure causes, become more pronounced. Range observation, even with the best-trained observers, becomes unreliable when the visibility is poor, and the errors in the range-finders themselves become greater as the range increases. From all these considerations it is evident that it is a matter of great difficulty to make an accurate forecast of the initial gun range and deflection. It has become the practice to obtain the hitting range by a process of "trial and error," using the gun as its own range-finder and obtaining what assistance is possible, under the prevailing conditions, from the available "instruments of observation." This can be done as long as the fall of the shot can be observed, but becomes impossible as soon as this condition ceases to exist. The use of aircraft to assist the spotter, or to carry out the whole of the observation of fire, naturally suggests itself; and it is in this direction, followed by the possible introduction of some form of indirect fire, that future developments are to be looked for. This must inevitably lead to complication and to the introduction of new instruments and methods of working. The increasing of the range must very much reduce the percentage of hits to be expected. This reduction in the probable number of hits, together with the increasing horizontal armour protection to be defeated, form the main arguments in favour of carrying larger guns.

Recent years have brought about a steady increase in the calibre of the guns that are mounted in capital ships; and in all the naval actions fought during the war experience has been in favour of the larger gun. There is still a trend towards further increasing the calibre of the guns, since victory will always rest with the side that can hit the harder at the longest range. The heavier the gun the greater the damage done by its shell, and the better its accuracy at extreme ranges. A limit in the size of the gun must, however, be reached when the weight of the ammunition begins to interfere seriously with the rapidity of fire. When this happens the call comes for an increased number of guns, and a limit is then imposed by the size of the ship.

The size of the guns in the secondary armaments has generally increased to meet the development of the destroyer and submarine. To obtain the necessary rapidity of fire, these guns must be hand-worked, and this fact places a limit on their size. It appears therefore that no increase in calibre is likely beyond the 6-in. and 5·5-in. guns that are now in general use in all navies.

In the decade before the war the 12-in. gun, firing a shell weighing between 800 and 900 lb., was the heavy gun that was almost universally mounted in the battleships of the world. The hitting power of these guns had been gradually increased by improving their ballistics, and no increase in calibre was made until after 1911. By this date the 12-in. gun had reached the limit of its development in the British navy in the 12-in. Mark XI. (50 cal.) gun.

The following summary shows how the gun armaments of warships of all classes gradually became heavier during 1910–20. The battleships of the "Colossus" class were armed with 10 12-in. Mark XI. guns, and 8 of the same guns were mounted in some of the contemporary battle-cruisers of the "New Zealand" class. The "Colossus" class were the last of the so-called "12-in. Dreadnoughts," and the midship turrets were placed *en échelon*, so that all the guns could be used on either broadside. This disposition of the main armament marks the transition stage to the centre-line arrangement, which by 1921 had been adopted in the capital ships of all navies. The secondary or anti-torpedo-boat armament in all these ships consisted of from 12 to 14 4-in. Q.F. or B.L. guns. The main armament of contemporary ships in foreign navies also consisted of 12-in. guns, but both the United States and Japan increased the number of the guns in their battleships to 12 as against the 10 in British ships. The secondary armament of the foreign ships was, at this period, usually heavier than the British, the Japanese having a mixed armament of 6-in. and 4·7-in. guns and the United States employing the 5-in. gun.

In 1912, the B.L. 13·5 Mark V. gun became the standard heavy gun for the capital ships of the British navy. It was introduced in order to increase the hitting power and also to obtain greater range, the demand for which was already being felt. This gun weighs 68 tons, and originally fired a shell of 1,250 lb. with a velocity of about 2,700 f.s. This was afterwards altered to a 1,400-lb. shell, with which a velocity of about 2,500 f.s. was obtained. Ten of these 13·5 guns formed the main armament of the battleships of the "Orion" and "King George V." classes, which were completed in 1912 and 1913 respectively. The battle-cruisers of the "Lion" class, which were completed at the same time, mounted 8 13·5 guns, and in both the battleships and the battle-cruisers all the guns were mounted on the centre line of the ships, so that all could be used on either broadside. As a secondary armament all these ships carry 14 or 16 4-in. B.L. guns. In the battleships of the "Iron Duke" class and the battle-cruiser "Tiger," which were completed in 1914, the main armament remained the same as in the previous ships, but an advance was made by increasing the secondary armament to 12 6-in. guns in the place of the 4-in. guns.

In both the U.S. and Japanese navies the 14-in. gun was mounted in all ships completed since 1914. This gun remained the standard weapon, in both navies, up to the ships that were building or projected in 1921, wherein a 16-in. gun was being adopted. The United States had retained a secondary armament of 5-in. guns, but in the American ships building in 1921 the 6-in. gun was to be mounted. Japan on the other hand, after having adhered to the 6-in. gun as the standard secondary armament weapon for her later ships, was in 1921 adopting a 5·5-in. gun.

The year 1915 marked further progress by the introduction of the 15-in. gun into the British navy. This gun weighs 100 tons and fires a 1,920-lb. shell with a muzzle velocity of about 2,500 f.s. These guns were used for the main armament of the 10 battleships of the "Queen Elizabeth" and "Royal Sovereign" classes. These ships mount 8 15-in. guns and have a secondary armament of 12 to 14

6-in. guns. The later battle-cruisers were also armed with the 15-in. gun, the "Renown" class having 6, with a reversion to the 4-in. gun, mounted on triple mountings, as a secondary armament. The "Hood," the latest type of battle-cruiser built after the battle of Jutland, mounts 8 15-in. guns with a secondary armament of 16 5·5-in. guns.

In the German navy the earlier battleships and battle-cruisers of the "Dreadnought" era were armed with the 11-in. gun, which for many years had been the heaviest gun employed in the German fleet. After 1912 the 12-in. gun became the standard weapon for the capital ships, and remained so until after the battle of Jutland. The secondary armament of all the earlier ships consisted of the 4·1-in. gun, but this was replaced in the later ships by the 5·9-in. gun. A few ships, designed to mount a 15-in. gun, were commenced for the German fleet in 1914, their armament being very similar to that of the British "Queen Elizabeth" class; only 2, the battleships "Baden" and "Bayern," were actually completed, but not until after the battle of Jutland. After the events of 1916, no outstanding developments in naval ordnance occurred in the German navy.

The battle-cruiser has replaced the armoured cruiser of the past, which has consequently disappeared from all modern navies. Similarly the "scout" and "3rd-class cruiser" type has developed into the modern light cruiser and this latter class has replaced the protected cruiser of the early years of the 20th century. The changes that took place in the armament of light cruisers during the war demonstrate the same constant demand for an increased armament as was apparent in the case of the capital ships. The first light cruisers proper, built for the British fleet, were the 6 vessels of the "Active" class, whose armament consisted of 10 4-in. B.L. guns. This class was followed by the larger "Bristol" type in which a pair of 6-in. guns were added. Then followed the 12 ships of the "Chatham" and "Birmingham" classes, again larger than their predecessors and mounting 8 or 9 6-in. B.L. and no 4-in. guns. The full speed of all these ships had remained constant at about 25 knots, but for tactical reasons smaller and faster ships became necessary. This resulted in the building of the "Arethusa" class, in which the armament was sacrificed to speed, and was reduced to a pair of 6-in. and 6 4-in. guns. These ships entered the fleet at the outbreak of the war in 1914 and were rapidly followed by the 12 "Calliope" class. In these latter ships the upward trend in armament commenced with the addition of a pair of 4-in. guns on each broadside. War experience soon demonstrated that the 4-in. gun was not powerful enough to inflict severe damage and was completely outranged by the 6-in. gun. Therefore the "Calliope" class were altered to mount 4 6-in. guns in the centre line, all the 4-in. guns being removed. At the same time a third 6-in. gun was added to the armament of the "Arethusa" class in the place of a pair of 4-in. guns. A similar process of rearming light cruisers was carried out simultaneously in the German fleet, by replacing the original 4-in. with 5·9-in. guns. All the light cruisers designed for the British fleet during the war had an armament of 6-in. guns only, mounted on the centre line. In the "Centaur" and "Carlisle" classes 5 of these guns are carried, and the "D" and "E" classes mount 6 and 7 respectively. The "Hawkins" class forms the extreme development of the light cruiser, for in these ships 7 7·5-in. B.L. guns are mounted, 6 of which can be fired on either broadside. These vessels are, however, of a special type. They are nearly twice the size of the previous light cruisers, being of about the same tonnage as the old armoured cruisers of the "County" class, though much faster and more powerfully armed. Another special type of ship, classed as light cruisers, were the 3 vessels of the "Courageous" class. These remarkable ships approached the capital ships in displacement, their weapons were of the same class, and they attained a speed of over 30 knots. To obtain this speed the armament and armour protection were reduced. Only two turrets, with 4 15-in. guns, were carried, with a secondary armament of 4-in. guns.[1]

In the case of the torpedo-boat destroyers the same gradual increase in gun armament is observable. Until 1910 the 12-pdr. gun was regarded as the heaviest gun that was necessary for a destroyer's armament, but after that date the 4-in. gun began to be used, on account of the increased size of the vessels themselves. At first one or two 4-in. guns were mounted in combination with the 12-pdr. but finally the 4-in. gun became the sole armament. The "K" and "L" classes, built in 1912–3, and the "M" class of 1914 all carried 3 4-in. guns. The "K" class mounted the 4-in. B.L. Mark VIII. gun and the "L" and "M" classes were armed with the 4-in. Q.F. Mark IV., which became the standard weapon for the many destroyers that were built during the first 3 years of the war. In the "V" class the armament consists of 4 4-in. Q.F. Mark V. guns, which are similar to the Mark IV. but more powerful. In the "W" class, which was built in 1918, a further advance was made by mounting 4·7-in. B.L. Mark I. guns.

Owing to the avoiding tactics invariably adopted by the Germans, most of the destroyer actions of the war developed into long-range combats rather than the short-range *mêlées* that had been expected. A number of alterations were therefore made in the armaments of British destroyers, to increase the elevation of the gun-mountings and the range at which the guns could be fought. All British destroyers are provided with one anti-aircraft gun. In the smaller vessels the Q.F. 2-pdr. Pom-pom is used for this purpose, but all the more modern destroyers carry a 3-in. H.A. gun on a specially designed mounting. The increase which took place in the armament of destroyers during the war is remarkable. Starting with the "L" class, with the 4-in. Q.F. Mark IV. gun (31-lb. shell), and a maximum range of 7,900 yd., successive advances have been made to the "W" class, with 4 4·7-in. B.L. Mark I. guns (50-lb. shell) and a range of 16,000 yd. Thus the weight of the broadside and the maximum range of the armament of the destroyers were more than doubled during the war.

The gun armament of British submarines was not developed on any very definite lines during the war. The submarines were used for attacking the enemy surface craft and submarines upon the high seas, and for scouting duties in the approaches to the enemy ports. For these duties no gun armament, other than a small H.A. gun for defence against aircraft, was usually necessary. In the German navy, on the contrary, guns were mounted in submarines for the specific purpose of attacking merchant ships, and the size of the guns was gradually increased, first from 3-in. to 4·1-in., and finally to 5·9-in. Before the war 12-pdr. guns had been mounted in British submarines, chiefly for high-angle fire against aircraft. During the war, guns up to 5·5-in. calibre were mounted in British submarines, in isolated cases for special operations in the Dardanelles, Black Sea and Baltic, but as a general rule the guns carried by these craft were confined to those required for defence against aircraft. When a gun armament is required for a submarine, the 4-in. Q.F. Mark XII., on a special mounting, is the normal gun now employed, in addition to a suitable H.A. armament. Several submarines have been built for the British navy which mount a single 12-in. gun. These vessels may be regarded as submersible monitors rather than true submarines, but this proves that it is technically possible to mount guns of practically any calibre in submarines, and undoubtedly the gun armament of future vessels of this type will depend on the development of the vessels, and the rôle they are designed to fill.

Monitors were a type of vessel that were built for a special purpose during the war, and their armament deserves a brief mention. The ships were designed solely for bombarding and for in-shore work. They were of shallow draught and slow speed, and were provided with special protection against damage by torpedoes. The armament consisted, in the larger vessels, of a pair of 12-in., 14-in. or 15-in. guns,[2] supplemented by a small anti-aircraft armament, and subsequently, in some of the ships, by a secondary armament of 6 to 8 6-in. or 4-in. guns. The smaller monitors had a single 9·2 or 7·5-in. gun, or a pair of 6-in. guns, with the addition of a small anti-aircraft armament. The guns and mountings in these ships were usually of an old pattern, alterations being made to allow for high angles of elevation in order to obtain the long ranges required. Special sighting and fire-control arrangements were also fitted to enable the ships to carry out bombardments by indirect fire. All these monitors were built in a very short time, to meet a special set of circumstances brought about by the war. They are a type of vessel not likely to be maintained during peace-time.

During the war a large number of small vessels were fitted out as patrol craft for anti-submarine work, and also for mine-sweeping and mine-laying. The majority of these were commercial craft (such as trawlers, drifters, tugs, etc.) which were converted and armed for their new duties; but a few types of ships came into being, which were specially built for this work. The armament was generally a small one, consisting, at first, of 3 and 6-pdr. guns and afterwards of 12-pdr. and 4-in. guns. At the end of the war a 4-in. gun was mounted in all patrol craft that were capable of carrying so large a gun, and a small anti-aircraft gun was also mounted when possible. Owing to the difficulty of inflicting serious damage on a submarine with a low-trajectory high-velocity gun, howitzers and bombthrowers (*see* p. 1212) were mounted in many of the vessels employed upon anti-submarine operations.

*Heavy Gun Mountings.*—Recent years have not brought about any very drastic changes in the main principles employed in the design of the turrets in which the heaviest guns are mounted in ships of war. The most recent designs of twin turrets in the British fleet show no very great difference in the general arrangements from those in which the 12-in. guns were mounted in the earlier battleships of the "Dreadnought" class. Such changes as have occurred have been caused by the general increase of the weight of the guns and ammunition that now have to be handled by the turret machines. The following description of the arrangement of a 15-in. turret can be taken as typical of modern British turrets for 12-in. guns and above. The salient features in which the turrets of other navies differ from the British are also pointed out.

The universal practice is to carry the moving turret structure inside a fixed circular armoured barbette on a ring of rollers which run upon a roller path built into the structure of the ship. The

[1] In the first two of the class. The third, the "Furious," was originally designed for 2 18-in. guns in 2 turrets, but during construction was altered to serve as an aircraft-carrier, and the forward turret was removed. Later the after turret was also removed, a secondary armament of 5·5-in. guns only being retained.

[2] The 18-in. guns released from the "Furious," as mentioned in footnote 1, were mounted under shields on 2 monitors.

armour of which this barbette is built varies in thickness from about 6 to about 12 in., according to the class of the ship, it being thicker in battleships than in battle-cruisers. The barbette extends, in depth, from a few feet above the level of the upper deck downwards through the various decks, and rests upon one of the horizontal armoured decks, usually at about the level of the load waterline of the ship. The lower tiers of the barbette armour are thinner than the upper ones, as they come behind the protection of the side armour of the ship. The turret structure is made to train round inside the barbette by a large pinion, carried in the revolving turret, which gears into a circular rack fixed to the structure of the ship. The revolving part of the turret is composed of 3 chief divisions:—(i.) the armoured gunhouse, in which the guns are mounted; (ii.) the working chamber, immediately below the gunhouse, in which the ammunition is worked; (iii.) the trunk, which extends down to the level of the magazines and shell rooms and is used for the transfer of the ammunition up to the working chamber.

The power used in the British navy for working the turrets is, at present, entirely hydraulic, supplied by hydraulic pumps which are situated outside the revolving structure of the turret. The Japanese and some of the German ships follow the British system, but in other navies electrical power has been used almost entirely for working the turret machines. Electrical turrets were tried in H.M.S. "Invincible" in 1912–3, but as they were not entirely satisfactory they were converted to the hydraulic system in 1914. The hydraulic system successfully withstood the severe test imposed upon it by the war, in the very large number of turrets afloat in the British fleet, and any other system will have to be proved to be very reliable before it can be expected to supplant it. Electrical machines have, however, made great strides in efficiency and reliability in recent years, and the combination of electric motors with hydraulic transmission (of the type of the Williams-Janney and Hele-Shaw machines) has rendered electric power peculiarly adaptable to turret machinery. This system has been used in all recent American and German turret designs, and the increased use of electrical power for the auxiliary and possibly for the main engines of warships may lead to the electro-hydraulic system being generally adopted in power-worked gun mountings.

If we take the before-mentioned 3 divisions of the turret separately, the detailed construction is as follows:—

(i.) *The Gunhouse.*—On the circular structure, which revolves on the roller path, is carried the shield of heavy armour for the protection of the guns and their mountings. The front and side plates of this shield are usually from 10 to 12 in. in thickness and sometimes even heavier. The rear plate is generally from 7 to 9 in. thick and the roof and floor plates from 3 to 5 in. The floor is extended to the rear, over the circumference of the barbette, in order to make room for the machines used for the loading operations and also to balance the turret. The guns are mounted, side by side, on separate slides, each gun being capable of moving independently of the other in elevation. Two pairs of very strong side transoms are built up on the floor of the gunhouse, and these carry on their upper parts the trunnion bearings for the gunslides. The gunslides are stiff girder structures, upon the upper surfaces of which the guns (trunnionless) are carried in cradles to which they are secured by steel straps. At the fore end of the slide are built 2 cheeks which carry the trunnions, and these latter work in the trunnion bearings of the transoms. The weights of the gun, cradle and slide, are so distributed that, when the gun is loaded and run out ready for firing, the whole is practically balanced about the trunnions. The elevating cylinder is fixed to the floor of the gun well, immediately under the slide, the piston rod being connected by a link to an arm which projects downwards for the lower part of the slide. The cradle, in which the gun rests, works in the direction of the axis of the gun, upon the upper surface of the 2 side girders of the slide. The recoil is controlled by 2 cylinders, fixed to the cradle one on each side of the gun, which contain a fluid, usually a mixture of glycerine and water. The piston rods are attached to the gunslide, and the piston head has a port cut in it which works over a valve key of varying depth. The flow of the liquid from one end of the cylinder to the other is thus gradually restricted during the recoil of the gun, which is thus brought to rest.

The gun and cradle are replaced in the firing position by pneumatic cylinders in the latest mountings, hydraulic power having been previously used for this purpose. Some automatic arrangement is always fitted for bringing the gun to rest gently, at the end of the running-out motion. The breech of the gun is operated either by hand or by an hydraulic cylinder mounted on the rear face of the gun, the power being supplied by means of telescopic pipes under the slide. A high-pressure airblast system is fitted, which automatically admits a blast of air into the gun as the breech is opened. This prevents the dangerous backflame that is liable to occur when firing to windward, when the breech is opened. A jet of water, under high pressure, is also blown into the gun as the breech is opened to quench any smouldering remains of the charge. An extension, called the loading arm, is bolted on to the rear end of the gunslide and carries a chain rammer and the machine for working it. The gun-loading cage, on coming up from the working chamber, is locked to the loading arm and moves with it as the slide is elevated. This admits of the gun being kept laid on the target whilst it is being loaded. In the rear of the gunhouse a small hydraulic crane is fitted for alternative loading. This crane can pick up shells from either of two positions, and place them upon a loading tray which can be secured to the loading arm when required. These two positions are the shell bins in the gunhouse behind each gun, where about 5 rounds per gun are stowed, and the shell bins in the working chamber below. The position of the officer of the turret is in the centre of the rear of the gunhouse, in an enclosed cabinet. Here the turret range-finder is mounted and the various instruments for control of fire and communications are situated. The gun sights are mounted on the slide trunnions, one on each side of each gun. The sighting ports are formed by 3 low hoods in the roof of the turret, the centre one containing the inner sights of both guns and the side positions the outer ones. Elevating and training control wheels are fitted in all the sighting positions, but the turret is usually trained from the centre, and each gun is laid for elevation at its own sighting position.

(ii.) *The Working Chamber.*—The working chamber is a circular space, usually from 10 to 12 ft. deep, immediately below the gunhouse. Its roof is formed by the gun wells, in which are the elevating cylinders and the telescopic pipes for taking pressure on to the gunslides. Below the floor of the working chamber is a compartment known as the walking pipe space. In this are situated the swivel or walking pipes by which the duplicated supply of pressure is taken from the fixed structure of the ship to the moving part of the turret. On the walls of the working chamber are arranged the leads of pressure piping and the groups of stop valves which control the admission of pressure to the different machines in the turret. In the working chamber are situated the 2 training engines, the presses for working the gun-loading cages, the alternative hand gear and other small machines for various purposes. There are also 2 shell bins in which about 8 shells for each gun are stowed, and holes are cut in the roof of the working chamber to enable these shells to be picked up by the crane in the gunhouse. The centre of the working chamber is occupied by the top of the trunk in which the ammunition is brought up from below. At each side of the top of the trunk are waiting positions, on to which the shell and cartridges are automatically discharged from the ammunition cages working in the trunk. From these waiting positions the ammunition is transferred, by hydraulic rammers, to the gun-loading cages; these latter, when in the down position, are in rear of the waiting trays and in line with them. The gun-loading cage consists of a tray upon which the shell is carried, and above this tray and to one side of it are 2 compartments, each of which carries a half-charge of cordite. The cage travels on a curved guide rail, and on being hoisted to the loading arm remains attached to it during the loading operation. When attached to the loading arm, the projectile tray of the gun-loading cage is in line with the bore of the gun, and the projectile is rammed into the gun by the hydraulically worked chain rammer carried on the loading arm. After the projectile has been rammed home the rammer is withdrawn, and the two half-charges of cordite are dropped in succession on to the tray which has been vacated by the projectile, and are pushed into the gun by the rammer. When the rammer is withdrawn after placing the last half-charge, the gun-loading cage is lowered to the working chamber in readiness to receive another round of ammunition from the waiting trays. A complete system of flashproof doors and screens is fitted between the gun-loading cage and the working chamber and also around the waiting trays and the top of the trunk. As far as possible, the whole path of the cordite, from the handing room to the gunhouse, is closed, so that the effects of an explosion in the gunhouse shall not be communicated, by way of the working chamber and the revolving trunk, to the magazines.

(iii.) *The Revolving Trunk.*—The trunk hangs from the floor of the working chamber, and, passing through circular holes in the different decks, is steadied at its lower end by lateral rollers. The lower end of the trunk is entirely free and supports no weight. At the centre of the bottom of the trunk, the electric and high-pressure air leads and also the voice pipes are passed from the fixed structure to the moving part of the turret. The trunk is divided into 5 compartments. In 2 large ones at the sides work the main ammunition cages, the space between them being occupied by the hydraulic presses for working these cages and by high-pressure-air bottles. In the rear compartment an auxiliary cordite hoist is fitted, and the front one forms an auxiliary shell hoist, which is also used as a ladder way for giving access from the shell room to the working chamber. At the magazine level there are openings in the trunk leading into the handing room, and the cordite compartments of the main cages are opposite these openings when they are in the lowest position. In the handing room, attached to the revolving trunk, are two loading hoppers which are fitted with flashtight doors. The cartridges are placed by hand into the hoppers, from which they are discharged into the cordite compartments of the main cage when the hopper doors are opened. The shell tray of the main cage comes opposite to openings in the trunk, at the shell-room level, to which sliding doors are fitted. Two shell bogies travel on racks round the outside of the trunk in the shell room, and are so arranged that they can be locked, either to the floor of the shell room, or to the revolving trunk. The shell are placed on the bogies by hydraulically worked grabs, and the bogies are then trained round by hand, until they are opposite the shell doors in the trunk. When the shell doors are opened, stops which hold the shell are released, and the shell rolls

through the door on to the projectile tray of the main cage. In the shell room the shell are stowed in bins, lying on their sides with their axes fore and aft. They thus start from rest in nearly the same position in which they are required for loading into the gun, and remain in this position during the whole of their course to the gunhouse. This is an important point when the shell that are being dealt with are over 5 ft. in length and weigh nearly a ton. Throughout the mounting elaborate interlocking gear is fitted between the working levers and the moving parts or the working valves of the different machines. This is to ensure that the various operations shall only take place in their proper sequence. Accidents are thus prevented, which, on account of the high speeds at which the heavy weights are worked, would be serious.

*American Varieties.*—The Japanese turrets follow generally upon the British model, but in the American designs there are essential differences, amongst which the following are the most noticeable. Electric power with hydraulic transmission is almost entirely used for working the machines, and no power other than the electric supply is brought into the turrets from outside. Inside the gunhouse the arrangement of the guns and slides is generally similar to that of the turrets of other navies, but the methods by which the various operations are performed are different. For instance, springs are almost invariably used for returning the guns to the firing position, and a large screw is used for elevating instead of an hydraulic cylinder. The breech is usually worked entirely by hand, and in the loading arrangements there are considerable differences from those of other turrets. The shell and cartridges are sent up to the guns separately: the former vertically in tubes on the outsides of the guns, and the latter by a central hoist placed in rear of and between the guns. The shell are transferred by hand to the horizontal position on arrival at the top of the vertical tubes, and are then rolled on to loading trays in rear of the guns. The cartridges are transferred by hand from the cartridge hoist to the same loading trays. Power-worked rammers are used for loading, which operation can only be carried out at a fixed elevation. The central part of the turret below the gunhouse is occupied by the arrangements for passing up the cartridges. This operation is carried out, to a great extent, by hand, and complete precautions against the passage of flash are fitted between the different compartments.

The shell arrangements differ entirely from those adopted by any other navy. The shell rooms consist of circular compartments which are built into the ship, just below the level of the lower part of the barbettes. The shells are stowed standing on their bases, instead of horizontally as is the custom in the turrets of other navies. The shell chamber in the turret, which is in the same relative position as the working chamber in British turrets, forms a revolving platform in the centre of the circular shell room. The shells are passed, still standing on their bases, from the fixed to the revolving part of the floor. From the shell chamber to the gunhouse the shells are carried up the vertical tubes in buckets. These buckets when loaded are balanced about their centres of gravity. On arrival at the top of the tubes the buckets are turned by hand into a horizontal position, and the shells are thus placed in the position required for loading into the gun. A noticeable feature of these turrets is the number of operations for which alternative hand gear is provided, and also the large number of small compartments into which the structure below the gunhouse is divided.

*German Varieties.*—The German turrets did not differ very greatly, in their main essentials, from the British, but were noticeable for their large gunports and for the somewhat cramped space inside the gunhouse. The loading arrangements differed, because, except in the case of the ships with 15-in. guns, the Krupp type of breech mechanism is used. With this type of mechanism the obturation entails the use of a brass cylinder for the rear cartridge of the charge. The projectile is supplied separately from the charge, in a cage on the outer side of each gun, whilst the cartridges come up to the gunhouse in cages between the guns. Both shell and cartridge cages are loaded in a working chamber under the gunhouse, the ammunition being supplied to the working chamber by cages working in a revolving trunk. The system of placing the rear cartridge in a brass cylinder has the disadvantage that, owing to their heat, the cylinders are heavy and difficult to handle after firing, and special arrangements have to be made for passing them out of the turret. These disadvantages are partially compensated for by the increased protection from flash which is given to the ammunition; and a very noticeable feature in the German turrets was the absence of flash-tight doors and other such arrangements for the prevention of the passage of flash to the magazines. The loading operation is carried out at a fixed angle of elevation. In the earlier German turrets ramming was carried out by hand only, but in the more modern designs a power rammer is fitted. The rate of fire that could be obtained with the German turrets appears to have been slightly greater than that with the British for short periods, but for prolonged firing the British system is surer and probably the quicker. The power used in the German turrets is hydraulic, supplemented by electrical gear to a greater extent than in the British service.

*Triple Turrets.*—In most foreign navies the triple turret has appeared, but the British navy has been slow to adopt this innovation. This development is due to the desire to increase the gun power of the capital ships, without unduly increasing the size of the ships themselves. Six guns mounted in 2 triple turrets occupy less of length of the ship, which is the important factor, than do the same number of guns mounted in 3 twin turrets. Designs of quadruple turrets have been produced, but it does not appear likely that the number of guns in a single turret will exceed three. It is not clear that economy of space would result from mounting more than 3 guns in one turret, on account of the large space that must be found immediately below the guns for the stowage of the ammunition. In the existing designs of triple turrets, the guns are placed side by side on the same level, and the loading and working of the breech of the centre gun present difficulties which must be solved if the rate of fire of this gun is to be the same as that of the other two. The methods of firing the guns mounted in multiple turrets, and the control of the fire, also present new problems which need investigation, but there seems little doubt that in the near future the triple turret will be adopted by all navies, for economy in space.

*Medium-heavy Guns.*—Few modern ships now mount a medium-heavy gun in either their main or their secondary armament. Guns of from 10 to 7 in. in calibre are not powerful enough to be of any real use as long-range weapons against armoured ships, and since their ammunition is too heavy to be man-handled they cannot be used for rapid fire and are consequently out of place in secondary armaments. The 10-in. gun has never been much used in the British navy, but at one period the 9·2-in. B.L. gun attained a high degree of favour. It formed the main armament of the armoured cruisers that immediately preceded the battle-cruisers, supplemented in some cases (*e.g.* the "Minotaur" class) by the 7·5-in. B.L. gun. The 9·2 B.L. gun also formed the secondary armament of the battleships of the "Lord Nelson" class, which was designed just before the "Dreadnought." Ships having a mixed armament of heavy and medium-heavy guns appeared in foreign navies at the same time as the "Lord Nelson," but since that time guns of medium calibre have not appeared in the armament of any capital ship. During the war, therefore, the 10-in. gun was scarcely used at all, and 9·2 and 7·5 in. guns were only mounted in a number of ships that were rapidly becoming obsolete, and also in a few small monitors, in which they were specially mounted for bombarding at moderate ranges. The relative weakness of the medium-calibre gun was well illustrated at the battle of the Falkland Is. when the German ships, armed with 8-in. guns, speedily fell victims to the greater range and hitting-power of the 12-in. guns of the British battle-cruisers.

The 7·5-in. gun has, however, been revived as the main armament of the "Hawkins" class, which is the largest type of modern British light cruiser. It was originally intended that the guns in these ships should be entirely hand-worked, and special arrangements were made for handling the 200-lb. projectiles. In the trial stage, however, it was found necessary to add power for working the elevating and training gear, in order to compete with the rapid motion of the ships. The gun is carried in a cradle through which it recoils, and the usual recoil cylinders and spring or pneumatic running-out arrangements are fitted. The trunnions of the cradle are carried in trunnion bearings on 2 side transoms built up on the floor of the mounting. The turntable is carried on a roller ring, and there is no vertical communication between the mounting and the lower part of the ship. All the ammunition arrangements are entirely separate and in general follow the usual practice for 6-in. guns. The shell and cartridges are brought up in separate hoists from below and from the tops of the hoists are carried to the guns by hand. A swinging loading tray is fitted on the rear part of the cradle and on to this the projectile is placed and the whole of the loading operation is carried out by hand. This is most fatiguing work with projectiles of this weight and there is little doubt that the mounting for any gun larger than 6 in. must be largely power-worked to be entirely satisfactory.

As the result of war experience, the mountings for the 6-in. and 5·5-in. guns have undergone a change in design, from the old pedestal (P.) mounting to the central pivot (C.P.) type. This has been caused by the necessity for increasing the elevation in order to obtain greater range. Also, mountings of the C.P. type have the added advantage that the base, which is fixed to the deck, is larger in diam. than is the case with P. mountings, and the severe stresses on firing are thus more evenly distributed to the structure of the ship. In the P. mountings the elevation was limited to from 15° to 20°, as the bottom of the cradle fouled the carriage and the breech of the gun hit the deck when firing at higher elevations. The elevation in this type of mounting can be increased either by lengthening the arms of the carriage or by raising the whole pedestal off the deck on a packing ring. Both these methods are objectionable, as they tend to raise the breech of the gun so far off the deck as to make loading a difficult matter when firing at moderate angles of elevation. But many such alterations were made to P. mountings during the war.

In the C.P. mountings a circular plate is bolted to the deck which has a low pivot in its centre. The circumference of the plate is shaped to form the lower roller path of the mounting, and inside this roller path a fixed circular training rack is fitted. Working round the pivot and carried on the rollers is the revolving platform of the mounting. The whole of the weight of the gun and mounting is taken on the rollers, the pivot being used only to prevent any lateral motion. Two side transoms are built up on the revolving platform, and at the top of these transoms are the trunnion bearings. Strengthening plates are built across the front of the transoms, but the rear

side is left open to allow the gun and cradle to swing in elevation. The cradle is fitted with trunnions, and the gun works axially through it on recoiling. The recoil is controlled as usual by a recoil cylinder containing a fluid and a piston with a gradually restricted port.

The gun is run out after firing, either by springs or by pneumatic recuperators. The elevating arc is attached to the centre of the lower part of the cradle (instead of to one side as in the P. mountings), and into it gears a pinion carried on a shaft working through bearings in the side transoms. This shaft is geared to the elevating control wheel, which is fitted in the gunlayers' position. The mounting is trained by a pinion which works in the circular rack on the inner side of the lower roller path, and which is geared to training wheels at the gunlayers' and trainers' positions. All the voice pipes and electrical cables are brought on to the mounting through the central pivot. In this particular the C.P. mountings are much more convenient than the P. mountings, as the number of these leads has been much increased during recent years. An extreme elevation of 30° or more is obtainable on the latest C.P. mountings, and the breech of the gun is between 50 and 60 in. off the deck when the gun is horizontal. To facilitate loading a swinging loading tray, having a motion parallel to the axis of the gun, is usually attached to the left rear end of the cradle. Special platforms are provided for the loading numbers for use when the gun is being loaded at moderate angles of elevation.

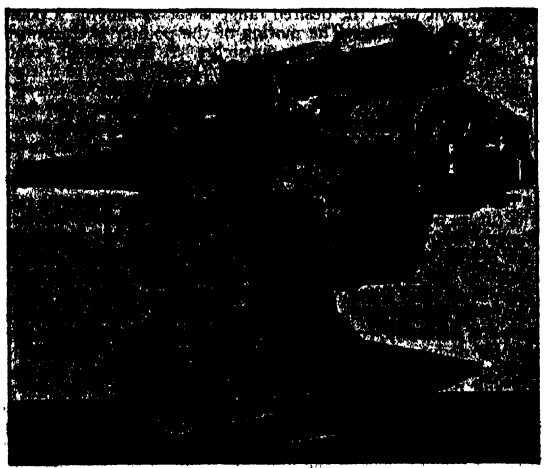

FIG. 48.—British 6-in. B.L. Mk. XII. gun on a Mk. XIV. C.P. mounting.

Typical mountings of this pattern are the British 6-in. C.P. XIV. and 5·5 C.P. II. The former is mounted in modern light cruisers and the latter is used in H.M.S. "Hood." Fig. 48 illustrates the 6-in. C.P. XIV. mounting.

*Guns of Lesser Calibre.*—The gun mountings used for the 4-in. and 4·7-in. guns have undergone a change from the P. to the C.P. type, similar to that which has taken place with the heavier guns, and for the same reasons. Guns of these calibres were used in large numbers during the war for two main purposes: (*a*) for the armaments of destroyers and other small craft; (*b*) for the defensive armament of merchant ships and auxiliaries.

For the destroyer armaments the guns that were used in the British service were the 4-in. Q.F. Marks IV. and V. and the 4·7-in B.L. Mark I. The two 4-in. guns are of the semi-automatic type, in which the recoil of the gun opens the breech and ejects the fired cartridge leaving the breech open, and the insertion of a new cartridge automatically closes the breech and puts the gun in the firing position. With these guns a rate of fire of from 15 to 20 rounds per min. can be obtained with a well-drilled crew. The 4-in. Q.F. Mark IV. gun was originally mounted on the P. IX. mounting, which is of the usual pedestal type with a maximum elevation of 20 degrees. The C.P. Mark III. mounting, which was subsequently introduced for this gun, is constructed on the same general principles as the C.P. mountings for the heavier guns, and admits of an elevation of 30 degrees. Certain modifications are introduced to suit the particular type of gun, and there are alterations in detail to meet the severe conditions that gun mountings are bound to be subjected to in destroyers. Both these mountings and all others designed for use in destroyers allow of a very long recoil, usually approaching 36 in. This is in order to minimize the deck stresses, which become serious when guns of this size are mounted in such lightly built craft. The 4-in. Q.F. Mark V. gun, which is heavier and more powerful than the Mark IV., is mounted on the C.P. Mark II. mounting, which is heavier than, but very similar in general design to, the C.P. III. and admits of an elevation of 30 degrees. The 4·7-in. B.L. Mark I. gun is mounted on the C.P. VI. mounting, which is a central pivot mounting very much like a small edition of the 5·5 C.P. II. The 4·7, being a B.L. gun, has its cartridges made up bare, with no brass cartridge case. A considerable saving in the weight of the ammunition is thus made but the rate of fire of this gun is less than that of the 4-in. Q.F. guns.

The very large numbers of guns required for the arming of merchant ships at the beginning of the war at first taxed the resources of the British navy to their utmost; in fact, at one period it became necessary to mount obsolete army guns on improvised naval mountings in order to provide some sort of armament. In the first two years of the war any guns of 6-in. calibre or smaller, that could be spared from other services, were adapted for defensively arming merchant ships. Subsequently the production, in bulk, of the 4·7-in. Q.F. Mark V. and the 4-in. B.L. Mark IX. guns provided a standard armament for this purpose. Both the mountings for these guns were made as simple as possible, as they had to be handled to a great extent by unskilled men. The 4·7-in. gun is mounted on the P.V. mounting, a simple mounting of the pedestal type, without a shield, which gives the gun an elevation of 20 degrees. The 4-in. B.L. Mark IX. gun is mounted on the C.P.I. mounting upon which an elevation of 30° can be obtained. The gun on this mounting can be protected by a shield, but when it was first used in merchant ships this shield was not used. Subsequently, however, the shield was added in these ships, partly for moral effect and partly for protection against the weather, but the mounting was shorn of all other complications (see fig. 49).

The usual control of fire fittings and a more elaborate sight than was found necessary in the merchant ships can be fitted to this mounting, and in this form it was used for arming sloops and other small ships. Large numbers of these two guns were produced in the last year of the war and they were used to replace the less efficient weapons that had been mounted in merchant ships. A triple mounting was made for the 4-in. B.L. Mark IX. gun and was used in the secondary armament of the battle-cruisers of the "Renown" class. In this mounting the guns are carried side by side in cradles which move together in elevation, on a mounting of the C.P. type. A few special mountings for 4-in. guns have been made for arming submarines. These are usually of the pedestal type, are constructed of non-corrosive metals and are specially designed to offer small resistance to the water when the submarine is submerged.

With regard to the smaller guns, the 3-pdr. and 6-pdr. may be considered to be obsolete except in very small craft. It is true that large numbers of these guns were used in the early part of the war because they were in existence and there was nothing at the time to take their place. Later they were replaced, almost entirely, by the 12-pdr. Q.F., large numbers of which were used for arming patrol craft, small merchant ships and auxiliaries. Several different pattern mountings were used for 12-pdr. guns, but all are of the pedestal type and most of them admit of an elevation of 30 degrees. The 12-pdr.

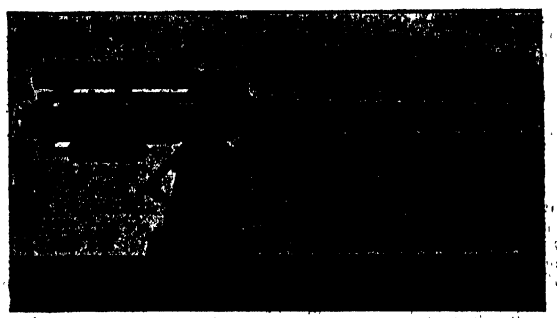

FIG. 49.—British 4-in. B.L. Mk. IX. gun on a Mk. I. C.P. mounting.

gun is usually laid, trained and fired by one man, elevating gear being fitted and the training being controlled by a shoulder-piece.

*High-Angle Mountings.*—The rapid development of aircraft has called for a new type of armament in the form of a high-angle gun. The commencement of the war found all nations unprepared to meet the new forms of attack that were quickly developed by the aircraft; and although the menace had been realized none of the belligerent nations had advanced much beyond the trial stages in the development of an anti-aircraft armament. The problem of hitting an airship or aeroplane is a difficult one, since the target is moving in 3 planes and at great speed. A vast amount of experience was obtained on shore during the war, but the problem is still far from being entirely solved. It is true that the high-angle gunfire succeeded in making the aircraft fly at a greater height, and therefore the attainment of their objectives has been rendered more difficult. At sea, much less experience has been gained and the problem is a much more difficult one, since the platform upon which the guns are mounted is a moving and unstable one and this adds immensely to the complications. The attack of aircraft necessitates the use of special shell and very accurate fuses, and it is with the latter that a large number of difficulties have occurred. At the outbreak of the

war high-angle armaments were called for at short notice and in large numbers. There was no opportunity of carrying out prolonged programmes of trials and consequently the ammunition used at first was faulty. Experience improved the material and the methods of using it, and by the end of the war the anti-aircraft guns were a factor to be seriously considered by the aircraft, although the problem at sea remains a very difficult one.

In 1914, a 3-in. Q.F. semi-automatic gun on a mounting capable of 85° of elevation had been completed for the British navy. This equipment, in slightly varying forms, became the chief anti-aircraft gun used in the British service, both ashore and afloat, during the first 3 years of the war. The gun is mounted on a roller-path mounting of the central pivot type, the trunnions being carried high enough to allow the gun to be fired at extreme elevation without the breech fouling the deck on recoil. The semi-automatic gun, with the cartridge and shell fixed together as one element, is used in order to obtain an extremely rapid rate of fire. Several modifications have been made to the original mountings to enable them to be used in small vessels such as destroyers and submarines. In these mountings the sight and the recoil and running-out cylinders are placed below the level of the gun and the mounting itself is simplified and made suitable for submersion in salt water by using non-corrosive metals. The running-out springs of all high-angle mountings have to be considerably strengthened to deal with the increased stresses at high angles of elevation and in some cases pneumatic recuperators are used instead of springs.

At the outbreak of the war, in order to provide a high-angle armament of some sort, a large number of gun mountings was rapidly converted so as to be able to fire at high angles of elevation. Within a few months all important ships in the British fleet were provided with two H.A. guns each, either proper equipments or conversions. The latter were, in no case, satisfactory and they were all replaced by proper H.A. guns as soon as these became available. In 1916 the increased activity of the enemy aircraft, and their more frequent appearance at sea, led to a demand for a larger H.A. gun than the 3-inch. The 4-in. Q.F. gun was brought into use, and was at first mounted on mountings designed for the 3-in. gun, which were suitably strengthened. The 4-in. H.A. Mark II. mounting was eventually introduced for the Q.F. Mark V. gun and this is at present the standard H.A. armament for all capital ships of the British navy. The mounting is, in general arrangement, a large edition of the original 3-in. H.A. mounting.

The indications are that the size of anti-aircraft guns will tend to increase. The first essential, however, of an efficient anti-aircraft gun is extreme rapidity of fire, and a limit is imposed on the size of the gun by the weight of the ammunition. A round of "fixed" ammunition for a 4·7-in. gun weighs about 80 lb. and this is as much as can be handled by one man with any degree of rapidity. It does not appear, therefore, that H.A. guns will increase much above this calibre, unless a complicated power-worked mounting is adopted. The chance of hitting the aircraft must be improved, and the extent of the menace of the aircraft to the capital ship will have to be more clearly defined before it can be anticipated that this step will be taken by any navy.

*Fire Control.*—The installation used for the control of the gunfire of warships had become increasingly intricate in the years before the war, and the experience gained during the war has made the addition of further complications necessary. Little can be said as to the details of the many instruments used, as the majority of them are confidential, and the functions, and even the existence, of some of them are kept as secret as possible. All nations are very reticent as to the actual systems employed in their ships. But the main problems are the same for all, and can be considered in 3 divisions:—(i.) the communications between the control stations and the guns, (ii.) the apparatus for obtaining the range and deflection and keeping them both correct, (iii.) the arrangements for firing the guns and observing the fall of the shot. These 3 sections must work in unison to form a perfect organization, and the system that is employed to make them do so must be able to withstand the stress of action conditions without breaking down. The methods employed to attain this are kept secret by all navies, and these methods are continually being altered and improved in detail, as the result of experience gained in practice and by the invention of new apparatus. In the following paragraphs a brief outline will be found of the principal instruments used in each section.

*Communications.*—The positions between which communication must be maintained are the observing positions aloft, the principal control position, which is usually in the vicinity of the conning tower, the turrets or other gun positions and the transmitting station. Communications must be rapid and sure as most of the information sent is only of value at the moment of transmission and loses its significance if any delay occurs. Hence several lines usually exist between important stations, any of which can be instantly used in the event of breakdown in the others. All lines of communication are usually concentrated from the outlying stations into the transmitting station. This station is situated in the centre of the ship, below the armoured deck, in the quietest position that can be selected and it forms the centre of the whole control organization.

Voice pipes are used to a great extent between stations that are permanently manned and are moderately close together. Their acoustic properties, however, become poor when the distances are increased beyond certain well-defined limits for each diam. of pipe or when there are bends in the lead of the pipes. Voice pipes are also difficult to make watertight or gastight.

The telephone is generally used between all stations, often in addition to the voice pipe. There is usually a telephone exchange, either in or near the transmitting station, for the sole use of the fire-control organization and independent of the general telephone system of the ship. Between important stations direct telephones, not connected to the exchange, are sometimes used. The actual transmitters and receivers are of many patterns, specially designed for operators who have other duties to perform or who may have to use the instruments in positions exposed to the weather. Electro-mechanical transmitters and receivers are used for passing range, deflection, bearing, orders and other information of a standard character between the control positions and the guns. There are several different patterns of these instruments, the most commonly used being the Barr and Stroud "step by step" and the Vickers "counter" types, both of which are in use in the ships of all navies. Frequently, with both these types a single transmitter is arranged to work a number of receivers in outlying stations and the uses to which the instruments can be put are manifold. A development of these instruments is found in the "follow the pointer" method, which is commonly used for transmitting ranges from the transmitting stations to the guns. Here the transmitter is in the form of a sight dial upon which the desired range is set by moving a pointer to the required setting. The motion of the pointer is transmitted electrically to a pointer on the gunsights. A mechanical pointer, geared to the mechanism which works the sight, is kept in line with the electric pointer and the sight is thus kept set without the sight-setter having to watch the movements of a separate instrument. This greatly simplifies the work of the sight-setter and eliminates errors. The large clock-faced dials and other similar arrangements that are often seen about the upperworks of warships are used for communicating the range and deflection in use to consorts who may be firing at the same target. Their place will probably be taken in the future by wireless telegraphy or telephony.

*Range Finding and Keeping.*—The transmitting station forms the centre of the whole control organization. In it are situated the majority of the calculating instruments, and through it are passed all the orders from the control officer to the guns. The functions of the majority of the instruments in the transmitting station and their details are, naturally, confidential. Broadly, they consist of arrangements for deducing the course and speed of the enemy from such data as may be available, and for calculating from this the change of range and deflection that should be applied to the gunsights. In the British service a calculating table, invented by Capt. F. C. Dreyer, is in general use, and to this improvements are continually being added to meet the changed conditions brought about by the increasing range at which the guns are used. The principles upon which this table is worked are secret, but there are other sets of apparatus, notably the Argo and the Ford, which have been patented and which aim at achieving the same results. Apart from the calculating apparatus, some form of which is in use in all navies, there are certain instruments employed generally for obtaining the required data, and a few of these can be mentioned.

*Range-Finders.*—The range-finder most commonly used in all navies is the Barr and Stroud coincidence instrument which has been in existence for a number of years (*see* RANGE-FINDERS). In the British navy this instrument proved its value during the war. To obtain greater accuracy at long ranges the length of the base of the range-finder has been increased from the original one metre to as much as 30 ft. The one-metre instrument is now employed only for navigational work and a 4½ or 9-ft. instrument is used in destroyers and other small ships. In light cruisers 9-ft. and 12-ft. instruments are used, and the 15-ft. instrument is in general use in capital ships. In some of the latest ships the base length has been increased to 30 ft., these instruments being usually mounted in turrets. The Barr and Stroud range-finder has been found to give generally satisfactory results, and any man with normally good eyesight can be trained to obtain accurate observations with it. In this it has a great advantage over the range-finders constructed on the stereoscopic principle, as used in the German and in some other navies.

To use one of these instruments it is necessary for the observer to have stereoscopic vision, a rare gift and one which varies in quality from day to day. A range-finder constructed on the sextant principle (Waymouth-Cooke) has been used to a considerable extent in destroyers. The instrument is small and handy, but the results obtained have been far from accurate and it is being superseded by the short-base Barr and Stroud instrument. At present there are at least 6 range-finders mounted in a capital ship for the use of the gunnery control, and this number is reduced proportionately in the light cruisers and smaller ships. In a capital ship one instrument is mounted in each turret and 2 others in positions aloft or above the level of the guns. The results of the observations of all the instruments are transmitted electrically to the transmitting station, where apparatus exists for rapidly obtaining a mean of the observations, thus giving what is called the "mean range-finder range." To this it is necessary to apply corrections for the density of the air, the effect of wind, the temperature of the charges and the nature of the

projectile, the change in the range during the time of flight of the projectile and for several other variables, in order to obtain the "gun range" with which fire is opened.

*Change-of-Range Calculators.*—When two ships are moving at high speed on different courses, the range between them is constantly changing at a varying rate. This rate of change of range can amount to upwards of 1,500 yd. per min. under action conditions, and it therefore is of great importance that it should be correctly known. The elements upon which the rate of change depend are the course and speed of the firing ship and the bearing, course and speed of the target. The first two of these are known, the third can be easily observed, but the last two are not known and can only be judged approximately. To obtain the rate at any given moment involves the solution of two triangles, the functions of which have just been mentioned. Several different types of calculators are in use for this purpose and that universally used in the British service is the Dumaresq, invented by Rear-Admi. L. S. Dumaresq. In this instrument the known and unknown elements are set graphically and the resulting rate of change of range, corresponding to the combination of the settings, is read off in "yards per minute," which is what is required. The speed of the enemy must always be guessed in the first place, but instruments known as inclinometers are being experimented with whereby the angle between the course of the target and either the line of fire or the course of the firing ship can be observed with fair accuracy at any moment.

*Range Clocks.*—Some type of clock which can be made to run at the rate of change of range is in use in all navies. In the British service the Vickers clock is used. This consists of a powerful clockwork escapement which drives a horizontal circular plate at a constant speed. Above this is a similar plate, the speed and direction of whose motion are controlled by the position of a friction roller mounted between the two plates. This roller is arranged to travel along a common diameter of the two plates. The motion of the upper plate can be varied from zero, when the roller is at the centre, to the maximum in either direction when the roller is at the ends of the radii. The pointer of the clock is geared to the upper plate and the face of the clock is graduated in yards. By altering the position of the roller the speed and direction of the pointer, in yd. per min., can be adjusted at will. Arrangements are made so that large corrections in range can be put on the perimeter of the clock without interfering with the motion of the pointer, so that the clock can always be run at the "gun range" that it is desired to transmit to the guns. This is the simple method of using the clock, but there are many other uses to which it can be applied.

*Deflection Calculators.*—It is a difficult matter to calculate the correct deflection for hitting a target at long range. The deflection depends, first, on the lateral motion given to the projectile by the speed of the firing ship. This is at its maximum when firing on the beam and vanishes when firing right ahead, but it is known and can be allowed for. Next comes the adjustment necessary for the movement of the target across the line of fire, between the moment of firing and the arrival of the projectile at the target. The amount of this correction depends on the distance and speed of the target and the angle between its course and the line of fire. This adjustment can be obtained with a fair degree of accuracy by calculation from the data that are used for obtaining the change of range, and a variety of deflection calculators are in use for this purpose. There is, however, a variable component caused by the effect of wind on the projectile. Allowance can be made for the wind at the firing ship, but at long range the wind effect at the target may be entirely different. Also the direction of the wind in the upper air, through which the trajectory of the projectile passes, is an unknown factor. All deflection calculators, therefore, have their limitations, and the usual practice is to calculate the proper setting as far as is possible and then to correct it by observation of the fall of shot.

*Bearing Indicators.*—These instruments are mounted in the control positions and are sometimes, as in the Evershed type used in the British navy, arranged to transmit the bearing of the target electrically to the guns and to the transmitting station. The instrument consists of a bearing plate, mounted with the zero adjusted to the fore-and-aft line of the ship, and graduated in degrees from 0 to 180 on each side. On the plate is mounted a telescope or binoculars. The movement of the telescope in azimuth, as it is kept trained on the target, works an electrical transmitter. The bearing of the target with reference to the fore-and-aft line of the firing ship is thus transmitted to the different stations. This forms a ready method of indicating the correct target to the guns, and from the observations the rate at which the bearing is changing can be obtained. This rate of change of bearing is used for calculating the course and speed of the enemy, and is also a measure of the deflection due to the relative movements of the firing ship and the target.

*Methods of Firing.*—Before the range at which heavy guns are used at sea became so extended, it was the practice to use a single gun for ranging before opening fire with the whole broadside. The differences between the shooting of individual guns, due to the wear of the guns, the temperature of the charges and a variety of other causes, become accentuated at long ranges and no two guns can be built that will always shoot precisely the same. This leads to a pattern or spread always resulting when a number of guns of the same size are fired at the same elevation. This "spread of the salvo," as it is called, can be reduced by making careful adjustments, but it can never be entirely eliminated. It can be made, however, an approximately constant quantity, known to the control officer of each individual ship. To base the corrections for the whole broadside on the result of the fall of the shot from a single gun, which may differ from the remainder, is obviously liable to lead to large errors. Also, at extreme ranges, the splash made by the fall of a single shot is difficult to see, even when using the best glasses. It is now the general practice to range with a salvo of several guns, usually half the broadside, and to continue firing alternate salvos of an equal number of guns. The object of the spotting officer, who knows the approximate spread that his salvos will give, is to apply such corrections as will bring the mean point of impact of his salvos on to the target. He then knows that he is obtaining the maximum hitting effect from the armament that he is controlling.

*Directors.*—Practically all navies have now adopted some form of master sight or director, whereby all guns that are loaded and laid at a prearranged elevation and training can be fired by a single gun-layer. Such a system of firing the guns has many obvious advantages, chief amongst which are the elimination of smoke interference of one gun with another, the reduction of the personal errors in laying and the fact that it is much easier to correct for the fall of a salvo that falls "all together" instead of being spread out over an irregular time interval. In the British navy the director installation invented by Admi. Sir Percy Scott is used. In this system a director sight is mounted aloft, or in a director tower well separated from the guns themselves. The sight is similar to the gunsight and all the usual settings can be made on it. The sight is carried on a mounting which is capable of being moved in elevation in the same manner as a gun mounting, but the efforts required for moving the sight are naturally much smaller than in the case of a mounting carrying a gun. The motion of the director mounting is communicated electrically to training and elevation receivers in the turrets or gun positions, thus causing the electrical pointers on the receivers to indicate the position of the director mounting. Mechanical pointers are fitted in the director elevation and training receivers at the guns, which are geared on to the moving parts of the gun and mounting.

The position of the gun in elevation and training is thus also indicated on the director receivers. By working the elevation and training control gears of the gun so that the mechanical pointers are kept in line with the electrical pointers, the guns are made to follow the motions of the director mounting. When the director is being used the range and deflection are set on the director sight and the director telescope is kept laid on the target by the director layer and trainer. The gunlayers and trainers at the guns keep their pointers in line for elevation and training, and the guns are thus laid to correspond with the position of the director sight. The firing circuits of all guns are brought to a single trigger at the director sight, so that all guns that are ready can be fired simultaneously by the director layer. This brief description indicates the principal functions of the director, but in actual practice there are many complications. The vertical and lateral distances of the director sight from the guns have to be allowed for and compensation has also to be made for any differences in the levelling of the gun mountings and of the director mountings. Arrangements are also necessary to compensate for the errors of the individual guns due to wear and other causes. On the whole the installation is an intricate one but the results that have been obtained have rendered it invaluable. In capital ships there are 2 director sights, which can be used alternatively for the main armament, one mounted aloft and the other in a position just above the level of the guns. A director sight is also fitted for use with the secondary armament. Light cruisers are fitted with a director for their main armament, and a modified form of director is in use in destroyers.

*Sights.*—The principles upon which the sights of naval guns are constructed have not been altered in recent years, but a great many alterations in the details have naturally been introduced to meet the requirements of the different types of gun mountings that have come into use. Telescopic sights are invariably used for all modern guns, the telescope being so arranged that, when the sight is set at zero, the axis of the telescope is exactly parallel to that of the bore of the gun. The telescope is carried in a carrier on a sight bracket and has two motions controlled by the adjusting mechanism of the sight. The angle between the axis of the telescope and the bore of the gun can be altered in the vertical plane to the angle of elevation for the required range. The range dial of the sight is graduated in yards to correspond to these angles of elevation; and when the telescope is laid on the target, its axis being horizontal, the axis of the gun is laid at the required angle of elevation. Similarly the telescope can be moved in the lateral plane through the number of degrees required for deflection; and when the telescope is then pointed at the target the gun is laid at the required angle to the right or left. The graduations of the deflection dials are sometimes in degrees and sometimes in knots, to the right or left, the latter being only exactly correct at a particular range.

Allowance is made for the permanent angle of drift of the projectile by fixing the whole sight bracket at a permanent angle to the vertical. The telescopes used are generally of variable power; that is, their magnification can be adjusted from about 3 to perhaps 20 diam., the high power being used for good visibility and the low power for

bad conditions. In the field of the telescope some mark is arranged to indicate the point to be brought on to the target in taking aim. The most usual form is a vertical and horizontal cross wire, across the diam. of the field, though in some cases arrows or circles are used. In telescopes intended for use at night, small electric lamps are fitted for illuminating the cross wires so that they and the target are shown up on a dark background. All telescopes are arranged so that they are not affected by the recoil of the gun and are placed as close as possible to the trunnions of the gun, or cradle, so that the motion of the gunlayer's head is limited although the gun may be moved through large angles of elevation.

In turrets the sight brackets are usually bolted directly on to the trunnions of the slide and rock with it, so that all backlash is eliminated. The sight bracket carries an arc upon which the telescope-carrier travels, and the position of the carrier on the arc determines the angle between the axis of the telescope and that of the bore of the gun. This angle is expressed in yd. on a dial which is geared to a rack on the arc of the sight bracket. The lateral motion for adjusting deflection is given to the telescope by pivoting its carrier at the front end of the bracket, and moving the rear end by gearing which is attached to the deflection dial. The whole of the deflection-setting gear is arranged to move in elevation with the telescope-carrier. Means are provided for adjusting the sight for the M.V. of the gun and for the temperature of the charge. This is usually effected by moving the zero position of the setting pointer of the sight.

At all hand-worked guns (except the smallest) 2 sights are fitted, one on the right and the other on the left of the gun. One of these sights, usually the left one, is used by the gunlayer, who fires the gun, for laying the gun in elevation, whilst the other is used by the trainer, whose duty it is to keep the vertical cross wire trained on the target. The two sights are cross-connected so that both can be set simultaneously for the range and deflection adjustments. The sights are mounted as close to the trunnions as possible to avoid undue motion of the heads of the gunlayer and trainer. In the most modern sights the telescope-carrier travels on an arc in much the same way as has been described for turret sights, but some types of sight are still in existence in which the front end of the carrier is pivoted and the rear end is given a vertical motion by suitable gearing.

A more complicated type of sight is needed for use with high-angle guns against aircraft. The target in this case is moving in 3 planes; that is, horizontally and laterally for range and deflection, and also vertically, this latter being usually described as the vertical deflection. The great speeds at which aircraft move in these 3 planes render the design of an accurate and easily set sight a difficult matter. During the war a number of high-angle sights were produced, most of them being of a makeshift character adapted for use with converted mountings. The problem of obtaining accurate gunfire at aircraft from guns mounted on the unstable platforms afforded by ships still remains to be solved, and the type of sight which will be adopted for this purpose still awaits the result of further investigation. Meanwhile many devices are in use for applying the range and the vertical as well as the horizontal deflection, but none of them can be said, up to the present, to meet all the conditions required.

Director sights are of the same general type as those of the guns that they are designed to fire, but there are additional devices fitted to compensate for various errors introduced by the distance of the master sight from the guns and to suit the details of the director mounting itself.

The electrical "follow the pointer" system of transmitting ranges and deflections to the guns, which is in general use and has been previously referred to, adds complications to the details of the design of the sights, but does not affect the principles.

*Naval Howitzers and Bombthrowers.*—A new class of naval ordnance was introduced in the latter part of the World War for use against submarines. This was the naval howitzer or, more particularly, bombthrower.

The early submarines were small in size, had little or no gun-power and were liable to damage by gunfire when on the surface. Consequently the first anti-submarine measures took the form of arming vessels with small guns. This had the effect of forcing the submarine to dive when within range of an armed vessel, and thus their movements were handicapped and successful torpedo attack was made more difficult. The submarine rapidly increased in size and commenced to carry larger guns, thus becoming much more formidable when on the surface. This led to the mounting of anti-submarine guns of larger calibre, but the submarine at all times offers a small and difficult target. Also, all but the very earliest boats are built with double hulls and are consequently very difficult to damage seriously by direct attack with the gun, owing to the "pressure" or inner hull being below the waterline.

From early days it had been realized that some form of under-water attack would be called for to counter the submarine, and as early as 1912 attempts were made to produce a diving shell. Extensive trials were carried out without success with the object of obtaining a projectile that would dive at low angles of descent when fired from a high-velocity gun with a flat trajectory.

Howitzers and bombthrowers were first tried during the investigation of the diving-shell problem in 1912, but the ranges obtained were considered, at that time, to be too small to be of value at sea. The question of the use of howitzers was reviewed at the outbreak of war, but the development of the submarine at that time was not such as to demand this form of weapon as a necessary counter-measure. It was not until after the pronounced increase in the size of the submarines in the latter part of 1916, that the question was seriously considered. It was at this time that the Sutton-Armstrong 3·5-in., 200-lb. stick bombthrower was developed as the first purely naval weapon of this type. The early part of 1917 produced an urgent demand for a simple form of howitzer for use afloat, to fire a shell or bomb which would dive and which could be rapidly manufactured in large numbers. This led to the introduction of the 5-in. howitzer, the 7·5-in. bombthrower, the 7·5-in. howitzer, the 10-in. bombthrower and the 11-in. howitzer, and at the same time experimental work was carried out with several naval weapons proposed by various inventors. The final development in the use of these weapons was their adaptation to fire the heavy external stickbomb, of the same type as that used in the 3·5-in. S.B.T. This greatly increased their effectiveness as anti-submarine weapons, and the use of these projectiles from all howitzers and bombthrowers was being extended when hostilities ceased.

The *3·5-in. Sutton-Armstrong stick bombthrower* was evolved from a model already in existence which had been designed for trench warfare. The bombthrower consists of a single tube with a trunnion ring screwed on to it. The tube screws into a spherical explosion chamber on which is a lateral extension carrying a simple swinging breech mechanism. To facilitate manufacture an improved design was introduced at a subsequent date, in which the sphesical explosion chamber was replaced by a cylindrical one with an axial, instead of a lateral, breech mechanism. The original bombthrower was fitted with a Temple silencer, with a view to preventing flash and noise when in the trenches. This being of no importance in naval conditions, the silencer was removed, but it had to be replaced by a "blast cone" and a "blast screen" was embodied in the design of the mounting, as without these accessories the gunlayer's seat was untenable owing to muzzle blast.

The bombthrower is carried in a revolving bracket which is mounted on a fixed pedestal. The extreme elevation obtainable is 55° and the low limit in the earlier mountings is 18°, but this was afterwards altered to 5 degrees. A simple aperture sight is carried on a bracket bolted to the right trunnion and the bombthrower is elevated by the usual rack-and-pinion gear worked by a hand-wheel. A downward blow of some 80 tons results from firing the bombthrower on this rigid non-recoil mounting, and the strain caused damage to the base plates and ship's structures when the bombthrowers were first mounted. This defect was remedied by increasing the base plate to 60 in. sq., thus distributing the blow on firing over a greater area.

The charge is contained in a small brass cartridge cylinder fitted with a percussion primer. The bomb when loaded rests in the blast cone at the muzzle. The stick occupies practically the whole length of the tube of the bombthrower, and is fitted at its lower end with a gas check. The accuracy of the bombthrower is excellent, a mean error of 30 yd. being obtained at 45° elevation and of only 20 yd. at 30° elevation. When the development of the submarine campaign called for a larger bursting charge in the bomb, a 350-lb. bomb was supplied for this bombthrower, which was fired with the same charge as the 200-lb. bomb. The accuracy with this heavy bomb is extraordinary, mean errors of 7 yd. at 45° elevation and of 19 yd. at 30° having been observed. A considerable number of these bombthrowers were mounted in small craft during the war, and they proved to be one of the most efficient of the anti-submarine weapons of this type employed.

The *5-in. breechloading howitzer* was a small single-tube breech-loading howitzer, designed for army use by the Elswick Ordnance Co., and adapted for use afloat. Their 50 and 40-lb. projectiles were too small for anti-submarine purposes, and the few of them that were mounted afloat were eventually withdrawn. Nevertheless they were the first weapons of the howitzer type that were actually mounted afloat for anti-submarine purposes.

Early in 1917 the necessity arose for a howitzer or bombthrower, for use afloat, which could be produced rapidly in large numbers and which was simple to handle and capable of a rapid rate of fire. The design chosen, from amongst others, was that of Messrs. Vickers for

a *7·5 bombthrower*. This design was subsequently altered to a *7·5-in. rifled howitzer*. Eventually a small number of bombthrowers and a large number of howitzers were made of this pattern, the non-recoil mountings in both cases being identical. In the design and supply of these two weapons, the overruling question was rapidity of production, and no time could be spared on refinements of design or finish. The result (fig. 50) was a roughly finished equipment which, although it served its purpose at the time, would not be repeated. It is extremely simple in construction and consists of a rifled "A" tube, with screwed breech and trunnion rings. The breech mechanism is of a simple B.L. type with a rifle-lock firing gear. The weapon is in reality a very simply constructed low-power breechloading gun. The *7·5 M.L. bombthrower* is similar in construction to the howitzer but is smooth-bored and a breech plug is used instead of a breech ring. A simple sliding breech mechanism is fitted and the charge is contained in a small brass cartridge case. The bomb is loaded from the muzzle and is fitted with vanes.

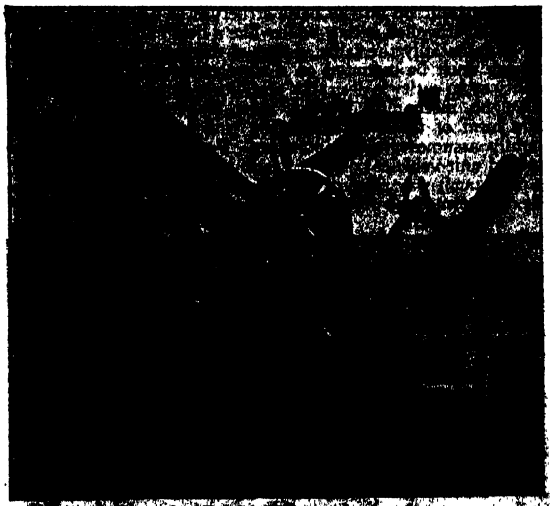

FIG. 50.—British R.M.L. 7·5-in. howitzer.

The mounting of the howitzer and bombthrower consists of a [illegible] which results in the [illegible] of the equipment. The lower surface of the carriage and the upper edge of the base plate are machined to form a training surface and the base plate is bolted to the deck. A strong all-round clip ring is fitted over the flanges of the base plate and the revolving carriage to hold the mounting to the base plate on firing. The effective blow transmitted to the deck on firing the howitzer on this rigid non-recoil mounting is large and necessitates very considerable strengthening to the ship's structure under the mounting. The elevating gear, as at first designed, consisted of a vertical screw, secured to a band round the breech of the gun and operated by suitable mechanism connected to the elevating wheel on the left of the mounting. On account of the distortion of the elevating screw by the firing stresses it was abandoned and a simple shoulder piece fixed to the gun itself, was adopted. A simple form of aperture sight is fitted. A rate of fire of 4 to 5 rounds a min. could be maintained with this howitzer; at one trial 20 aimed rounds were fired in 3½ min. with an untrained crew.

The main object for which these equipments were designed was achieved, as no less than 650 of them were actually mounted afloat within a year of the design being called for.

The *10-in. R.M.L. bombthrower* was a bombthrower of novel type which was evolved from a design produced by Messrs. Thornycroft (fig. 51). The bombthrower consists essentially of 2 parts, the explosion chamber and the barrel, the former being placed on top of the latter and secured to it by steel straps. The charge is burnt in a perforated combustion chamber secured inside the front end of the explosion chamber. The gases, after expansion in the explosion chamber, pass downward through a dowel in the rear end into the rear end of the barrel. The charge is contained in a small brass cylinder and is loaded at the front end of the explosion chamber, which is fitted with a simple sliding breech mechanism. The bomb is loaded from the muzzle and is fitted with six studs which engage in the rifling grooves in the barrel. The 10-in. bombthrower which was used in the British navy (the actual design of which was produced by Messrs. Vickers) is built up of a number of parts. This was done in order to make use of the shell-making plant which was available at the time. The non-recoil mounting is similar to that of the 7·5 howitzer in general design but is fitted with a stronger clip ring and powerful elevating gear. At the trials of the first of these weapons difficulty was experienced in determining a satisfactory charge. Very high pressures, which appeared to follow no known laws, were experienced in the explosion and combustion chambers, and it was only after a long series of trials that a suitable charge and design of combustion chamber were obtained by "trial and error." Though designed especially for rapid production to fulfil an emergency requirement, manufacturing difficulties rendered the results disappointing.

The *11-in. howitzer* was introduced in order to provide armed merchant cruisers and large vessels generally with a quick-firing anti-submarine gun of considerable size and firing a heavy projectile. The howitzer is built up and consists of an "A" tube, jacket and breech ring. The breech mechanism is of the Asbury type and is fitted with a rifle-firing mechanism. The mounting is a recoil one of more elaborate type than those of the other howitzers and bombthrowers, it being a roller-path mounting with cross-connected sights, hydraulic recoil, spring run-out and a loading tray geared to a quadrantal rack. The accuracy is very good, a mean error of only 17 yd. being obtained at 44° of elevation; and the errors in range at the lower angles of elevation are even smaller. Two reduced charges are used which also give good accuracy, and by using suitable charges the projectile can be made to [illegible] at a minimum range of 2253 yd. A considerable number of these equipments were installed in vessels employed on convoy duties during the war.

The 6-in. Newton bombthrower [illegible] to give free and elastic support to the gun. [illegible] spherical cast-iron dish, the breech end of the gun being [illegible] of the dish. On recoil the gun set back hard on the [illegible] dish and the latter being very massive, the blow on recoil was largely absorbed by it, only a light stress being transmitted to the deck structure. A central stud was fitted at the bottom of the barrel to form a stop for the bomb when loaded. The barrel was mounted in a sleeve which formed the trunnions and attached to the barrel was a control arm carrying the laying handles and sights. This equipment as a whole proved unsuitable for service afloat, but the bombthrower itself was an unsatisfactory weapon and this fact possibly obscured any good points which might have appeared in the principle of the mounting.

*Heavy Stick Bombs.*—Early in 1918 it became increasingly evident that projectiles with a heavier bursting charge than those in use in the existing howitzers and bombthrowers were necessary if any real damage was to be done to submarines. A heavy projectile which would dive at short ranges was required and this led to the introduction of the heavy stick bomb. A hydrostatic fuse is used in these bombs, to fire the bomb when it arrives at a predetermined depth below the surface. In all trials the accuracy was very good and it was found possible to use the same charge as when using [illegible] projectiles in the same weapon, thus [illegible] in supply and drill. The trials [illegible] by firing the lighter bombs [illegible] full charge, down [illegible] the bomb with [illegible] approximating to that of the [illegible] projectile weapons. Many [illegible]

out to perfect the fuses and detonating arrangements of these large bombs, and supply in bulk was about to be made to the service afloat when hostilities ended.

During the last six months of the World War it became increasingly necessary to introduce some method of throwing a heavy explosive charge to a distance of 150 yd. or more. The use of the stick bombs was therefore applied to the smaller guns, and a series of trials, carried out in June and July 1918, showed that the same stick bombs as were used in the howitzers and bombthrowers could be fired from guns of 4·7-in. calibre and below. It thus became possible to supply to these guns a projectile which contained a burster of the same order as that of a depth charge. Measures were at once taken to supply these projectiles generally, but unavoidable delays occurred in manufacture, and it was not till Nov. 1918 that [illegible] bombs of this class began on a large scale. (S. T. H. W.)

## (VIII.) Anti-Aircraft Equipments

On the advent of aircraft in practical offensive operations, it was found that the existing types of artillery equipment, both mobile and fixed, were hopelessly deficient in the essential qualities necessary for effective results. The speed and height at which aircraft operate are factors of great importance, as they combine to cause a considerable angular displacement during the time of flight of a projectile. The essential characteristics

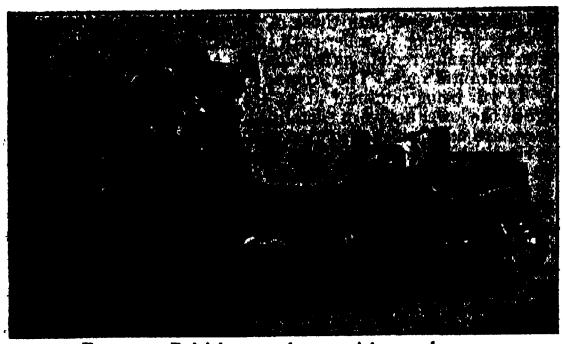

Fig. 52.—British 3-ton lorry, with 12-pdr. gun.

required in a gun are high velocity, high rate of fire and capability of being loaded at any angle of elevation, including means to prevent the round slipping back after loading. And the carriage must be designed to permit of the gun being loaded, laid and fired at all angles of elevation and traverse. The design must ensure a level platform so that, for accuracy of fire, the gun may pivot truly in the vertical and horizontal planes.

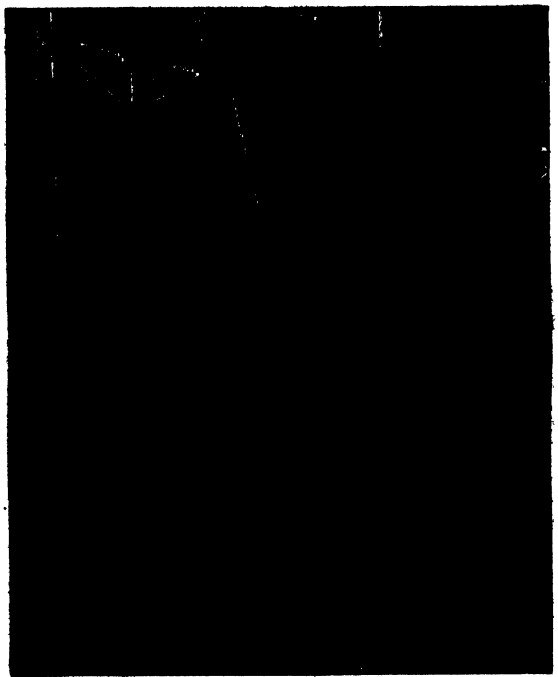

Fig. 53.—Schneider 105-mm. gun, on anti-aircraft mounting. Firing position.

Few specially designed A.A. equipments existed in any country and of these the greater part were constructed for fixed emplacements. In some countries these were augmented by makeshift mountings which usually consisted in a framework of pivot and platform in which the service field gun and carriage could be placed bodily. Soon, however, it became apparent that mobile as well as fixed guns were required.

To meet this need the British adapted a certain number of 13-pdr. and 18-pdr. guns, which were mounted on motor lorries. These answered the purpose for a time, but in view of the necessity for a gun having a higher M.V. than these, the 13-pdr. of 9 cwt. was evolved. This gun was practically a combination of the two: externally, its dimensions were those of the 18-pdr., and internally it had the bore of a 13-pdr. and chamber of an 18-pdr.; that is to say, it fired the 13-pdr. shell with the 18-pdr. charge. The breech mechanism was practically the same as that of the 18-pdr. field gun with the addition of a cartridge-retaining catch, but the striker was modified so as to be cocked automatically on opening the breech.

With fixed mountings the requirements of the carriage can be met by designing the intermediate carriage to permit of the high elevation, and mounting it on live rollers on a base ring to give all-round traverse. The base ring is secured by bolts to anchoring plates embedded in a concrete emplacement, additional nuts for levelling being provided.

The design of a mobile carriage is limited principally as regards weight. The pre-war attempts to design a mobile anti-aircraft carriage were largely adaptations of the field carriage, for example the Deport 75-mm. combined field and anti-aircraft equipment.

But the limited traverse and elevation which are inherent drawbacks in a field carriage prevent the mobile anti-aircraft equipment from being built up on the basic structure of a trail, axletree and wheels, and travelled with a limber like a field carriage. The design must be essentially the same as that of the fixed mounting, but the base ring must be mounted on a wheeled structure; further, road mobility as an entity is desirable, and, horse-draught not being up to the weight, mechanical traction must be resorted to.

The form of track as defined by rail, road and cross-country naturally assumes great importance. For railway travelling self-propelled unit-vehicles could be readily constructed; but restriction to a permanent way renders their use impracticable on a fluid front, while, for permanent defences, fixed mountings would be used.

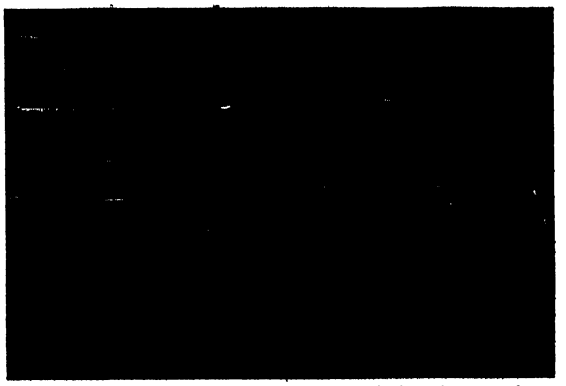

Fig. 54.—Schneider 105-mm. gun, on anti-aircraft mounting. Travelling position.

For road mobility there are two alternatives: a self-propelled vehicle such as the motor-lorry or a tractor-drawn vehicle. In accordance with the law governing the maximum axle-load, the weight restricts the use of the lorry to comparatively light equipments. Thus, for the mounting of medium guns a special type of travelling platform, lorry-drawn, is generally employed.

For cross-country travelling ordinary wheels are useless, the prevailing method being to employ caterpillars or wheels running on chain tracks. In this connexion the automobile type of vehicle may be utilised for light guns; but for medium guns the base ring of the mounting would probably be supported on a framework pivoted on the axles of a tractor-drawn, caterpillar mount.

The types of wheeled structure which have been evolved may be given as follows: the motor-lorry, the travelling platform with detachable axles and rubber-tired wheels, the caterpillar truck.

The 3-ton lorry (fig. 52), the first type of wheeled structure to be used, was employed as a travelling and firing platform for the 12-pdr. coast-defence gun and the 13-pdr. horse-artillery gun, both of which were adapted to a suitable pedestal mount fixed to the lorry.

With intent to maintain approximately a constant load on the steering wheels whether the vehicle be empty or loaded, the lorry is designed on the cantilever principle. This ensures easy steering, but entails the whole of the useful load being borne by the rear axle. To preserve this principle, the pedestal was fixed to a steel base plate bolted to the chassis frame directly over the rear axle. When travelling the springs of the lorry act to reduce travelling stresses; but as a stable and level platform is necessary for firing, the gun cannot be fired off the lorry wheels. For this purpose, the lorry is supported on 4 adjustable screws mounted at the ends of steel beams fitted to the underside of the chassis; the screws rest on packing pieces, and are manipulated until the weight is taken off the wheels and the platform levelled.

For light equipments and travelling on good roads, the lorry is a convenient platform, as it provides the tractive power and carries the gun, ammunition, stores and personnel within one vehicle. The latest equipment to be mounted on a 5-ton lorry is the 3-in. mounting modified to take the 13-pdr., 9-cwt. gun.

The travelling platform proper was designed to render mobile a mounting which was already in use in fixed defences; it is limited to the use of good roads. The platform, a rectangular steel structure, is mounted for travelling on a pair of detachable axle-arms carrying rubber-tired wheels. Adjustable screws pass through nuts at the extremities of arms hinged to each corner, and these arms are swung outwards to extend the base for firing; while, for travelling, the arms at one end are removed, the others being swung inwards and coupled to a motor-lorry. For firing, the platform is first raised by the screws and the wheels and axles removed; it is then lowered on to the ground and levelled. The underside is fitted with anchoring plates which, in conjunction with steel pickets, fix the platform for firing. The mounting is traversed on a circular base ring bolted to the platform.

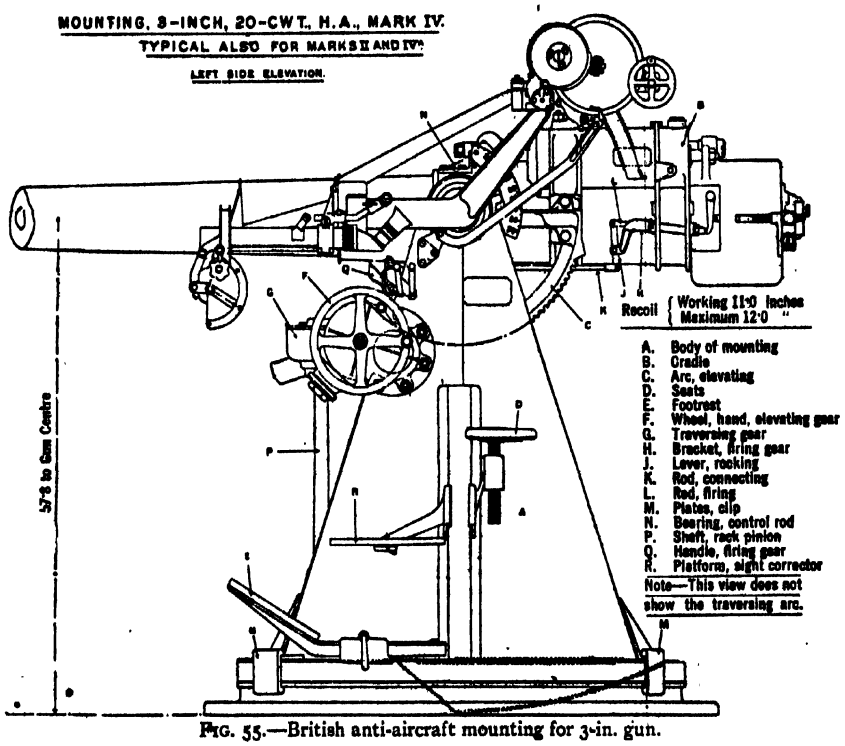

FIG. 55.—British anti-aircraft mounting for 3-in. gun.

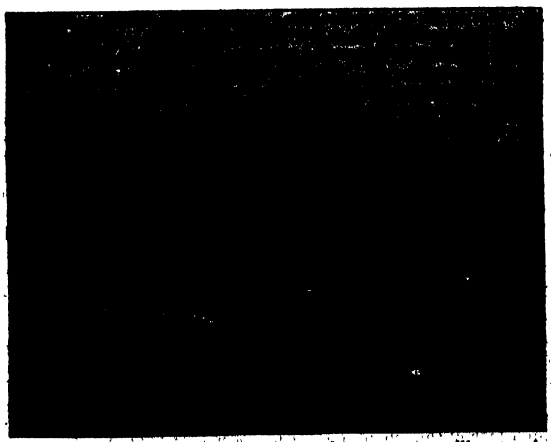

FIG. 56.—3·6-in. anti-aircraft mounting, on caterpillar truck.

Figs. 53 and 54, showing the Schneider 105-mm. (4·2-in.) equipment, model 1918, illustrate this form of anti-aircraft mounting. In fig. 53 the gun is in the firing and in fig. 54 in the travelling position. The ballistic and other particulars of this gun are as follows: calibre 105 mm.; length overall 42½ cals.; weight of shell 37½ lb.; M.V. 2,760 f.s.; range 15,400 yd.; weight of gun 36 cwt.; travelling weight of gun and mounting (inclusive of limber perch) 9½ tons; weight of system in action 8 tons, including shield.

The caterpillar truck as a travelling and firing support owes its introduction to two reasons: first, the need for travelling an equipment over other than good roads; and secondly, to enable a heavier and more powerful mobile gun to be employed.

The truck used with the British 3·6-in. gun described below is approximately 15 tons in total weight and is tractor-drawn (fig. 56.)

The truck frame or platform, which consists of 4 transverse and 2 longitudinal girders, is adjustably mounted to permit of 9° longitudinal and 5° transverse levelling. A screw-operated steadying arm is hinged to each corner of the truck for use when firing; these arms are swung outwards and operated until they bear on the ground, the weight being then distributed over the arms and roller chains. A base ring is bolted to the top of the frame.

The caterpillar truck is least mobile of the 3 types, but does not restrict the equipment to road travelling. It has an advantage in that the gun is fired off the roller-chains and steadying arms—unlike the platform proper, with which the wheels and axles must be removed for firing; while the levelling arrangements, though more complicated, are an improvement on the earlier adjusting screws.

As regards the mounting itself, the general principles of design may be illustrated by the British 3 in. (fig. 55). This may be either fixed or mobile, and the gun can be loaded and fired at any angle up to 90° of elevation, the height of the trunnions (nearly 5 ft.) giving clearance for the breech of the gun when firing at high elevations. The carriage is traversed on a live roller-ring which runs on the base ring, and is controlled by suitable gear. The ring cradle has a hydraulic buffer, spring recuperators, and is pivoted on trunnion roller-bearings at the top of the intermediate carriage; the elevation is controlled through gearing in mesh with two arcs underneath the cradle. Seats, foot-rests and trays for the convenience of the layers are adjustably attached to the intermediate carriage. The sights are of the rocking-bar type, and cross-connected to permit of dual control. When mounted in fixed defences, a training indicator, correctly oriented, is fixed to the emplacement floor.

The 4-in. mounting is generally similar to the 3-in., but, on account of weight, is used for fixed defences only. The gun can be fired up to 80° of elevation but must be depressed to 60° for loading. It has a tapered rod buffer and a hydro-pneumatic recuperator consisting in one liquid and two liquid-and-air cylinders.

The 3·6-in. mounting, designed on the rear-trunnioned principle, permits of all-round traverse and a maximum elevation of 90°. It may be either fixed (when it is mounted on a pedestal), or mounted on a caterpillar truck as here shown in fig. 56. By adopting the rear-trunnion system, employing a ring-cradle, and rearwardly extending the intermediate carriage at the top, the gun is carried in a relatively low position which permits of loading from the ground, gives a maximum clearance for recoil, and increases the stability. Balancing springs are fitted under the front of the cradle to overcome the muzzle preponderance; and to balance the intermediate carriage, when on a caterpillar mount, an extension to carry a counterweight is formed at its front end. The traversing gear is a 2-speed worm-and-rack drive. The elevating gears, of which one is operated on each side to embody the principle of the independent line of sight, are worm-and-arc-pinion drives. The recoil and recuperative arrangements consist in a rotary piston buffer with separate recoil and running-up valves, and a hydro-pneumatic recuperator of the floating piston type. The buffer is fitted with a spring-loaded tank and the recoils are controlled according to the elevation of the gun.

(F. M. R.)

**OREGON** (*see* 20.242*).—The pop. of Oregon in 1920 was 783,380 as against 672,756 in 1910, an increase of 110,624 or 16·4% as compared with an increase of 62·7% during the preceding decade. The average number of inhabitants to the sq. m. in 1920 was 8·2 as against 7 in 1910. The sparsely settled areas, other than the national forests, are the plateau region of the south-eastern counties and the extreme south-western county. In all the south-eastern counties, excepting Malheur county lying along the Snake river, there was a decrease in pop. during the decade. The density of the rural pop. in the nine south-

**These figures indicate the volume and page number of the previous article.*

eastern counties, comprising an area of 47,737 sq. m., or about one-half the state, was less than 2 per sq. mile. The urban pop. of the 23 cities and towns with more than 2,500 inhabitants each numbered 391,019 or 49·9% of the total pop. as against 45·6% in 1910. The farm pop. in 1920 was 293,432 or 37.5% of the total in the state; in 1910, 41 per cent.

The following are the cities of over 7,000 inhabitants with their pop. in 1920 and 1910 and percentage of increase for the decade:—

| | 1920 | 1910 | Increase per cent |
|---|---|---|---|
| Astoria | 14,027 | 9,599 | 46·1 |
| Baker | 7,729 | 6,742 | 14·6 |
| Eugene | 10,593 | 9,009 | 17·6 |
| Pendleton | 7,387 | 4,460 | 65·6 |
| Portland | 258,288 | 207,214 | 24·6 |
| Salem | 17,679 | 14,094 | 25·4 |

*Forestry.*—The total wooded area of the state in 1920 was 41,111 sq. m., or 43% of the land area; there were 14 national forests with a total area of 24,086 sq. miles. However, as some of the lands within the boundaries of the national forests are privately owned or classified as chiefly valuable for agricultural purposes and open to homestead entry, the net area of national forest lands June 30 1920 was 20,472 sq. m., or 13,106,676 acres. Broadly speaking, the national forests cover the Cascade range, the Coast range, the Blue Mountains, and other mountainous areas. From the coast to the eastern base of the Cascade Mountains the state is heavily timbered, except for the farming lands and clearings in the Willamette, Rogue river and other minor valleys. The conservation policy carried out through the establishment of national forests had in view not only permanent forestry but also the protection of the water-supply for power, irrigation, navigation and domestic uses. While the large forest area of the state gives Oregon one-fifth of the standing timber in the country, it also ensures it 11% of the total hydro-electric power capable of development. The estimate for the state is a potential maximum of 6,500,000 H.P. and a minimum of 3,000,000 H.P. The reservation of the national forest areas does not preclude large utilization for stock-raising. The east slope of the Cascade Mountains and the mountainous regions of the eastern part of the state are grazed by both sheep and cattle, over 2,900 permits being issued by the Forest Service in 1920 for 120,000 head of cattle and 690,000 sheep. The seasons for grazing in the forests are comparatively short, but the feed is excellent and is available at a time when the live stock must be removed from farm lands to permit crops to grow, and therefore these Government-owned ranges are an economic asset of much importance.

*Agriculture.*—Of the total land area of the state 22·1%, or 13,542,318 ac., were included in 1920 in the 50,206 farms. Of this land, 36·5% was improved. There was an increase during the decade of 10·37% in the number of farms, 15% in their total acreage and 14·9% in the improved acreage. The personnel operating the farms included 49,633 white farmers and 573 of non-white races. Of the white farmers 40,484 were native and 9,149 were foreign-born, 31,569 of the native white farmers being owners, 802 managers and 8,113 tenants. The 573 non-white farmers included 15 negroes, 300 Indians, 224 Japanese and 34 Chinese; 358 were owners, 8 managers and 207 tenants. Eighty-one per cent of the Oregon farms were operated by the owners. During the decade 1910–20 the value of the farm property increased 55%; of land and buildings 48·2%; implements and machinery 214·8%; and live stock 71·2%. The average value of land and buildings per farm was $13,449 as compared with $10,012 in 1910; the value of the land alone per acre was in 1920 $43.29 as against $35.23 in 1910. Of the farms from which mortgage reports were obtained the mortgage debt was 31·2% of their value as against 22·6% in 1910. The average rate of interest paid was 6·5%. In 1910 33·7% of all farms operated by their owners were mortgaged while in 1920 the proportion had risen to 49·7%. The debt per farm was $3,622 in 1920. The crop values in 1920 were 192·7% higher than in 1910. The conspicuous increases were in the production of forage, of ensilage, and of fruits of every kind adapted to Oregon conditions. In 1920 the principal field crops with their values were as follows:—

| | | | |
|---|---|---|---|
| Winter wheat | $33,213,659 | Potatoes | $ 7,829,867 |
| Spring wheat | 9,366,703 | Corn | 2,429,132 |
| Oats | 8,162,649 | Rye | 1,778,474 |
| Barley | 2,503,536 | Hay | 32,906,225 |
| | | Hops | 3,960,000 |

The total field crops were worth $106,185,746.

The principal fruits raised, with their values, were as follows:—

| | | | |
|---|---|---|---|
| Apples | $3,210,653 | Loganberries | $1,953,720 |
| Pears | 1,236,980 | Strawberries | 1,260,000 |
| Prunes | 4,126,950 | Raspberries and blackberries | 1,800,000 |
| Cherries | 1,234,500 | Nuts | 606,000 |

The total for all fruit was $15,787,803.

The numbers and values of domestic animals were as follows:—

| | | |
|---|---|---|
| Horses and mules | 286,000 | $23,266,000 |
| Milch cows | 205,000 | 15,375,000 |
| Other cattle | 651,000 | 24,412,000 |
| Sheep | 2,270,000 | 15,663,000 |
| Swine | 272,000 | 3,482,000 |

*Mining.*—The production of gold was $633,407 in 1911, but increased to $1,902,179 in 1916, to drop again to slightly over one million dollars in 1919. Silver to the value of $250,597 was produced in 1919. The copper output in 1919 amounted to 2,808,017 lb. fine. Iron has been mined and smelted in Clackamas county and considerable bodies of a good grade of limonite have been discovered and are being developed in the northern Coast range in Columbia county. Some manganese was produced during the World War, the chief occurrence being manganese oxides in a reddish volcanic tuff in Jackson county. The production of chrome ore was also stimulated by the war conditions and an output of 18,454 long tons of chromite brought $855,050. Nickel ore occurs in Douglas county and both tungsten ores and molybdenite in Wallowa and Baker counties. Although there are coal outcroppings in different sections of the state the output in 1918 had dropped to 13,328 short tons. Common clay wares in 1918 brought $232,564.

*Industries.*—Oregon has two important advantages for manufacturing: an abundance of such raw materials as timber, live stock, wool, wheat and fruit, and also readily available hydro-electric power. A relatively high transportation cost to reach a large body of consumers has been the factor handicapping development. In 1914 Oregon's manufactured products were valued at $109,761,951 and the average number of wage-earners employed was 28,829. The chief industries arranged in order of value of products were lumber and timber products, slaughtering and meat-packing, dairy products, printing and publishing, canning and preserving. The annual lumber production is from 2,250,000,000 ft. to 3,000,000,000 ft. and is rapidly growing. During the war, in connexion with the emergency shipbuilding programme, 44 steel hulls, with a total tonnage of 345,700 dead-weight, were launched and 13 hulls were on the ways. Beginning with the launchings in 1916, by Dec. 31 1918 145 wooden hulls, with a total tonnage of 446,100 dead-weight, were placed in the water and 50 hulls were on the ways.

*Transportation.*—The marked improvement in transportation facilities during the decade 1910–20 comprised the opening of the main waterways, extension of the railways so that the mileage increased by more than one-half, and a relatively extensive construction of highways. With the completion of the Celilo canal by the Federal Government in 1915 the Columbia and its tributary, the Snake, were made navigable to Lewiston, Idaho. Through the construction of this canal above the city of The Dalles a fall of 80 ft. in a stretch of 9 m. was overcome. With the transference to the national Government in 1915 of the canal and locks around the Willamette Falls at Oregon City, the free use of the upper Willamette was secured. As already stated, the coöperation of the Federal Government and the port of Portland secured a deep-water channel in the Columbia from Portland to the sea. The railway construction during the decade has provided: (1) lines to the Pacific coast, from Portland to Tillamook and from Eugene to Coos Bay; (2) extensions into central Oregon with parallel lines up the Deschutes river to Bend and westward from Vale in the Snake river valley; (3) construction on the gap between Natron and Klamath Falls as part of a double line for Oregon-California traffic; (4) electric lines from Portland to Eugene and from Corvallis to Eugene. The railway mileage in the state in 1910 was 2,413·61; in 1920 3,626·77.

The total of the sums apportioned to Oregon for highway construction by the Federal Government was $6,206,799.27. Bond issues by the state for the construction of a state highway system were authorized, beginning with the year 1917, to the amount of $40,000,000. During the biennium 1919–20 the cost of state highway work under construction [illegible]. Appropriations for market roads by the state [illegible] counties [illegible] state funds available for [illegible] Oregon [illegible] among all the states. [illegible] to the limit of 6% of [illegible] highway improvement, and since 1913 32 counties [illegible] themselves [illegible]

*Education.*—Oregon [illegible] amendments [illegible] by the [illegible] education. As [illegible] those of [illegible] teaching [illegible] minimum length of the school sessions has been extended to eight months for every district. The amount of money which the poorest district in the state must have for school expenditures was in 1921 $940. The requirements for certification to teach in the elementary grades include the work of a standard high school and in addition an elementary teachers' training course. After 1925 the teacher will be required to have had one year of normal-school work in addition to high-school preparation. In 1920 the total enrolment of grade and high-school pupils was 148,412, of whom 22,954 were in high schools. As the pop. of the state was 783,380, nearly 19% were in school, and 2·9% of the entire pop., or 15·4% of the school pop., were enrolled

in high school. The largest city, Portland, leads all cities of the nation with 3·6% of its pop. in high school.

*History.*—The percentage of Oregon's contributions of men to the World War without awaiting the operation of the selective service law was the highest among the states. The ratio of its enlistments to the first gross quota was 157·84 per cent.

During 1910–20, recourse was freely had to the "Oregon System" of direct legislation to enact projects of constitutional amendment and statutory law. A total of 174 proposals was submitted to the people through initiative petition, referendum petition or by vote of the Legislature and 73 were approved.

The people of Oregon by this procedure established prohibition, woman suffrage and the rural credit system. Citizenship qualification for the franchise, the right to veto single items in appropriation bills, the abolition of the poll tax, classification of property for taxation, and state-wide limitation of the rate of increase of taxation and indebtedness were also thus enacted. But the most striking achievement through this procedure by popular vote was the regular and liberal support of institutions of higher education as well as of the public schools in the form of continuing state millage taxes. These were granted by an overwhelming majority vote of the people. There has been a change in the attitude of the people with respect to direct legislation; a project submitted by vote of the Legislative Assembly has fared better in recent years than one submitted by initiative petition. Clearly demonstrated advisability is required to secure the approval of an initiated project, whereas originally there was a prejudice in favour of such a measure. Probably the most important new departure has been the liberal authorization of the use of the public credit, both state and county, for road-building, of the credit of port districts for harbour improvement, and of the credit of irrigation and drainage districts and of deforested land districts for reclamation. Additional legislation included the establishment of the minimum wage, workmen's compensation, "blue sky law," licensing sales of corporation securities, and widow pensioning.

While three-fifths of the voters usually vote with the Republican party, so that as a rule only 10 or 12 Democrats are elected to any Legislative Assembly, the representative leaders of the Oregon public during 1910–20 were two Democrats, George E. Chamberlain as U.S. senator and Oswald West as governor. Mr. Chamberlain was promoted from the governorship to the Senate; and in the Senate he was distinguished for his independence, especially during the war as chairman of the Senate Committee on Military Affairs. Oswald West, as governor (1911–5), deserves high credit for leadership in achieving much of the progressive legislation enacted during this period, and for his administration of the state penitentiary and the selection of those placed in charge of other state institutions; also for his application of the honour system among convicts and his insistence on a regimen of industry and cleanliness in the Oregon penitentiary.

During the decade 1910–20 the people of Oregon began to demand more active progress in their state government. While there had been before 1910 a half-hearted venture in railway regulation, later repudiated, and institutions of higher education had been receiving meagre support for some decades, the spirit of the constitution of 1857 was still dominant. That document had been drafted by men with whom the disastrous experiences of the Mississippi valley states in canal and railway building with borrowed money were fresh in mind. In recent years, however, the desire of an early realization in Oregon of an adequate highway system, and the assured prospect of regular revenues from automobile licences, led to the authorization in 1917 of a state bond issue for the building of a state highway system. The limit then fixed was 2% of the assessed valuation. This limit was raised in 1920 to 4% for the state. With the bonds voted by the Legislature at the 1921 session this limit was reached. The counties are authorised to borrow up to 6% of assessed valuation to secure funds for highway improvement. Oregon's contribution to the U. S. forces in the World War was 41,671 officers and men, and the amount raised in Liberty and Victory loans $28,409,350.

The recent governors were: Oswald West (Dem.) 1911–5; James Withycombe (Rep.) 1915– . (F. G. Y.)

**ORELLI, HANS KONRAD VON** (1846–1912), Swiss theologian (*see* 20.251), died at Basel Nov. 6 1912.

**ORKNEY and SHETLAND** (*see* 20.279 and 24.853).—Before the World War, British naval bases in the conflicts with France, Spain and Holland had been ports in the south of England, but the rise of the naval power of Germany in the first years of the 20th century created a new situation; the northern coasts became the important naval front, and the North Sea the probable scene of naval operations. Before the outbreak of war Scapa Flow was selected as a forward base, and in Aug. 1914 it became the headquarters of the Grand Fleet. The entire Orkney and Shetland region was an important military area throughout the war, and the ports of Kirkwall, Stromness and Lerwick proved to be of the utmost value for the conduct of the blockade. After the adoption of the principle known as "the continuous voyage," first for contraband of war and then for all goods, the cargoes of neutral vessels had to undergo a careful scrutiny in order to ascertain if Germany was the ultimate destination of any of the goods carried in a ship. The large cargoes carried by modern steamers rendered it impossible to conduct this examination at sea, and they were sent into port. For this purpose, Kirkwall, Stromness and Lerwick were very frequently employed. The large and temporary naval population brought great commercial prosperity during the war years; travel to Orkney and Shetland was prohibited except under special permits.

**ORLANDO, VITTORIO EMANUELE** (1860– ), Italian statesman, was born in 1860. Becoming a barrister and a law professor, he was first elected deputy for Partinico in Sicily in 1898. He was Minister of Education in the Giolitti-Tittoni Cabinet of 1903–5, and of Justice in the Giolitti Cabinet of 1907–9, and again under Salandra in March 1914. Although a Giolittian at heart, he was in favour of intervention in the World War at a time when many other politicians still hesitated and most of his party were decided neutralists. On the resignation of the Salandra Cabinet in July 1916 he remained in office under Boselli as Minister of the Interior. His administration of that department left much to be desired, as he permitted the Socialists to conduct a defeatist propaganda which was largely responsible for Caporetto. But on the resignation of Boselli, Oct. 29 1917, Orlando was entrusted with the formation of the new Cabinet, and the course of events imposed on him a somewhat more energetic internal policy. He was Prime Minister at the time of the peace treaty, but his Cabinet fell June 20 1919, owing to his failure to secure a settlement in Paris. On Dec. 3 he was elected President of the Chamber.

**ORPEN, SIR WILLIAM** (1878– ), British painter, was born at Stillorgan, co. Dublin, Nov. 27 1878, and studied at the Dublin Metropolitan School of Art and at the Slade School, London. He was elected A.R.A. in 1910, and R.A. in 1919. He first exhibited at the New English Art Club, of which he became a member in 1900, his early work being marked by preoccupation with spacing and silhouette and the use of quiet harmonies of grey and brown, with a note of vivid red or blue. He soon turned to the use of bright colour and the study of light, seen in a series of brilliant portrait interiors such as the "Hon. Percy Wyndham" (1907), "Myself and Venus" (1910, now in Pittsburg Gallery, U.S.A.) and the "Countess of Crawford and Balcarres" (1914). At this time he produced a series of figure compositions, mainly of a satiric and fantastic character, such as "The Passing of his Lordship" and "A Western Wedding" (1914), and became well known for his vigorously characterized portraits, generally marked by the use of much reflected light in the shadows, recent examples of which are "Lady Bonham Carter" (1917), "M. Clemenceau" (1921), and "The Chef" (1921 R.A. Diploma work). To landscape he paid comparatively little attention. During the World War he received a special appointment as official artist, and in 1918 an exhibition of his war pictures was held in London. The same year he was created K.B.E. Many of these pictures were subsequently presented by the artist to the nation, and are now in the Imperial War Museum. They consist of a large number of military portraits, and a series of landscape and figure studies from the western front, marked by extreme competence in the choice and employment of means, but representing the reduction of previous experience into a skilfully handled recipe. Orpen's satiric bent and summary method sometimes bring his portraits near to caricature; and his predilection for silhouette and bizarre pattern is apt to reduce his figure and landscape work to a series of flat shapes without substance and weight, as may be seen in his two Peace Conference pictures, exhibited in 1919 at the Royal Academy. He is represented in the Tate Gallery by three typical portraits, and a water-colour drawing.

**ORTHOPAEDIC SURGERY.**—The branch of surgery known as Orthopaedic (Gr. ὀρθός, straight, and παῖς, child) has long out-

grown its etymological meaning. It now deals with the adult as well as the child. Until comparatively recently it embraced only congenital deformities of children, lateral curvature, acquired deformities of the feet, deformities due to rickets and infantile paralysis, and to certain types of ankylosis. More recently it has included tubercular and other infective diseases of joints, both in children and in adults. The experiences of the World War of 1914–8 considerably broadened its definition, and revealed the fact that the teaching of orthopaedic surgery had been very deficient—more particularly in the treatment of injuries of the extremities. Visits to command depots and certain military hospitals convinced the British authorities of the necessity of starting a series of large hospitals all over the British Isles; these were first called "orthopaedic centres" and later "special military surgical centres." They were situated in London, Liverpool, Manchester, Leeds, Newcastle, Oxford, Reading, Cardiff, Bristol, Bath, Edinburgh, Glasgow, Aberdeen, Dublin and Belfast. These hospitals were staffed by men trained in orthopaedic surgery, by general surgeons and neurologists, and were equipped with every modern facility for the practice of reconstructive surgery, including physiotherapy departments, gymnasia and vocational curative workshops. The group of cases treated at the orthopaedic centres consisted of:—fractures (recent, malunited and ununited); paralyses due to injury of the peripheral nerves; paralyses due to injuries of the central nervous system; diseases, derangements and disabilities of joints, including the spine; deformities due to the contractions of scars and to injuries of muscles; functional diseases requiring reëducation. Later, limb-fitting centres were attached to several of these hospitals.

The wisdom of creating these centres was soon apparent. Derelicts poured in from all parts of the country, and soldiers who had been discharged with deformity were readmitted for treatment. The value of segregating cases in masses under surgeons specially trained for the work was clearly demonstrated. The experiment started in Liverpool with 250 beds, and the expansion was so rapid that in less than 12 months 21,000 beds were under orthopaedic control.

After the war there was a movement in all parts of Great Britain to improve the training in orthopaedic surgery, and to increase in scope and number the special departments attached to universities and medical schools, and to simplify and make more thorough the treatment of fractures. The fact that 50% of the wounded in the war of 1914–8 received injuries resulting in impairment of locomotor function and usefulness of limbs, brought the importance of orthopaedic principles and methods of treatment into great prominence.

Orthopaedic surgery may now be said to include:—(*a*) Congenital and acquired deformities of the spine and extremities; (*b*) infantile paralysis after the acute stage; (*c*) the deformities of adult paralysis; (*d*) stiff and ankylosed joints; (*e*) torticollis ("wry-neck"); (*f*) diseases of joints and disabilities, such as rupture of crucial ligaments, injuries to semilunar cartilage, snapping hip, slipping patellæ, and those conditions which are included under the aggressive title of "bonesetting."

The war enabled surgeons to formulate conclusions based on the observation of large groups of cases, and to obtain information likely to be of great value when dealing with industrial cases. The suture of divided peripheral nerves will serve as an example. In pre-war days, an experienced surgeon in the course of a life-time rarely saw more than 20 cases. During the war many surgeons sutured over 500 nerves, and the successful issue was due largely to the experiences gained by orthopaedic surgeons in the treatment of the paralysis of infants. From the nature of the injuries and the prolonged suppuration that followed, operation often had to be postponed for many months, and only after the removal of all cicatricial tissue was it safe to operate owing to what is called latent sepsis. Germs which remained quiescent, when disturbed by the knife assumed activity —often of a very virulent type. In other cases, muscle had to be freed and developed, and diseased areas of bone drastically extirpated before a nerve could be sutured. These operations required great delicacy and judgment. It was found by experience that in most cases it was possible to bring the nerve-ends together even after the destruction of a considerable area. This was sometimes effected by posturing the joints in order to lessen tension. In other cases the nerves were transposed from their bed and made to take a shorter course. In other instances the operation was done in stages in order gradually to stretch the nerve. Many methods which were formerly used to protect the injured nerve from injury during healing by adhesions were discarded in favour of surrounding the sutured ends by living tissue. Nerve grafting—*i.e.* utilizing a portion of a cutaneous nerve to bridge the gap in a motor nerve, proved a failure. Equally abortive were all attempts at grafting foreign material, nerve anastomosis, and the turning down of flaps. The great lesson learnt was that end-to-end suture is the only method to adopt in the immediate future.

A very remarkable adaptation of orthopaedic experience to injuries of the war was the transplantation of tendons in conditions of irreparable injury to the nerve. This was most useful in the cases where the musculospiral nerve was so destroyed as to render suture impossible. As a result of this injury the function of the hand was greatly impaired. The musculospiral nerve governs the motion of all the muscles which extend the wrist and the fingers. Destruction of the nerve paralysed all the muscles, and the victim, if he wished to extend the wrist and fingers, had to do it by using the other hand.

Orthopaedic surgeons had been accustomed for many years to utilize any spare active muscles, in cases of infantile paralysis, in order to take the place and assume the action of the muscles which were paralysed. For instance, a muscle group whose function was to evert the foot (*peronei*), if found paralysed, would be replaced by one of the invertors of the foot (*tibialis anticus*). This muscle would be dissected from its insertion halfway to its origin, and taken from the inner side of the foot and planted into the bone on the outer side. The child would then be trained to use the muscle so that when it acted it would assume the function of the paralysed muscle. This principle was adopted on a very large scale in all the orthopaedic centres to supply a remedy for the paralysed extensors of the wrist and hand. Certain muscles would be taken from the front of the forearm, one of which would be attached to the paralysed thumb, another to the extensors of the wrist, and another to the various extensors of the fingers. In this way, some hundreds of cases experienced a complete restoration of the function of the hand.

The influence of physiology or psychology as it affects the transplanted muscle deserves comment. It is very difficult to explain how a muscle which has always acted as an invertor should respond to a command to evert. After a little education, however, the will becomes the master of the situation, and the transplanted tendons display an admirable functional adaptation. A few soldiers suffered from the destruction of the obdurator nerve with a resulting paralysis of the quadriceps—a muscle whose function it is to extend the leg. In order to regain that function, two of the muscles from behind the knee are brought to the front of the thigh and fastened into the knee-cap to replace the quadriceps. In this way again, muscles, which normally bend the knee, take up a new action and straighten it.

Another orthopaedic principle derived from the treatment of infantile paralysis and utilized for war injuries is known as tendon fixation. An example can be given by an irreparable injury of the sciatic nerve. All the muscles below the knee are paralysed. There are therefore none that can be transplanted, and the foot remains flail. In such cases, the paralysed tendons are utilized to sling the foot to the bones of the lower leg. Certain tendons in front of the foot are cut below their origin and fixed in a tunnel bored into the bone, while the tendo Achillis at the back is treated in a similar manner. The foot is thus slung into a good carrying position, and cumbersome braces discarded.

The history of damaged joints is hardly less interesting. The wounds of the war were often so extensive that joints were not only destroyed but large pieces of bone were carried away, so that the arm or leg dangled in flail fashion. As an example, the case of the shoulder will serve to illustrate our procedure in dealing with other joints. The arm lies limp at the side—there is no power to lift, laterally deflect or rotate it. Experience in treating infantile paralysis in children has supplied an idea by which the limb can be made useful. The procedure is known as arthrodesis. Although the arm cannot move, the shoulder-blade can. The surgeon attaches the bone of the arm (humerus) to the shoulder-blade and allows both bones to become united. The arm is fixed in the most useful position in relation to the shoulder-blade; the muscles which hitherto only moved the shoulder-blade will now move the arm also. By this device the patient is able to feed himself, lift his arm from his side, put his hand in his pocket and perform many useful functions.

Again, the orthopaedic surgeon may have to deal with a stiff or ankylosed joint. In the case of the hip, shoulder or elbow, there are at his command methods to mobilize them by forming new joints. The hip-joint will serve as an example. The destroyed joint is cut down upon, the socket reconstructed, the head of the thigh-bone reshaped, and soft muscular and fascial tissue utilized as a buffer between the bones in order to imitate nature. The war has brought about the perfection of such methods, enabling flail joints to be stiffened, and mobilizing those which are ankylosed.

Bone grafting has been much simplified, and has been largely used in the surgery of the jaws and in ununited fractures of every kind. Gaps of four and five inches have been remedied by this means, and certain technical details have been perfected which have given the transplanted bone greater viability. It has been most useful in fractures below the knee and in the forearm. Cases are on record where the graft has been broken and has united again, as in the case of a

simple fracture. Grafts have also lived in the presence of suppuration. The shin-bone (tibia) is the favourite quarry from which the grafted bone is taken. A point of great interest is that the grafted bone often develops until it assumes the thickness and contour of the bone which it supplants.

No branch of surgery has been so much advanced by the war as fractures. Before the war, the treatment of fractures in England was little less than a reproach. Fractures of the femur, unless operated upon, generally displayed a shortening of about two inches. This was largely due to faulty education of the student, and the early evacuation of fractures from hospital wards. There was usually no considered after-treatment. Few surgeons knew the uses of the Thomas splint which, for simplicity and efficacy, surpassed any appliance in any of the armies. There was no effort in the first stage of the war to standardize this splint or to segregate fractures. This resulted in a great mortality, and filled the orthopaedic centres with appalling deformities. Fractures of the femur will serve as an example. In the early phases of the war the mortality from these fractures was 80%. Later, when fractures were segregated at the base and the Thomas splint applied in the firing line, this mortality was reduced to 20%. The standardization of the Thomas splint, the education of men in its use, and its application on the field of battle, secured for the fracture immobilization and simplified treatment; it minimized shock, and it prevented the perforation of vessels by securing the alignment of the broken ends. Its use had to be understood from the field to the base hospitals, for continuity of treatment was imperative. At the base hospital it might be necessary to apply modifications in more leisurely fashion. At a later date these fractures were admitted directly into orthopaedic centres, and, as a result of investigation, it was found that out of several hundreds of cases the average shortening did not exceed half an inch. These results in the British army were incomparably better than those in any of the other armies. The important lessons learnt from these experiences are: The necessity of better training of students, the standardization of the most efficient splints, the segregation of cases under men versed in mechanical principles, and the securing of efficient orthopaedic after-care in order to obtain function.

Further experiences gained in orthopaedic hospitals included the radical treatment of the chronic sinuses leading to diseased bone. Instead of simple procedures to remove dead bone, a very extensive operation was generally performed. All unsound bone, not merely dead bone, was removed, and the edges of the large cavities bevelled down in order that the soft tissues might fill the cavity. This thorough treatment often reduced healing to weeks instead of years. Malunited fractures again formed a large group in the orthopaedic centres. Surgery has now sufficiently advanced that, under favourable conditions, deformity should not occur. The orthopaedic teaching emphasizes the fact that good function is its end and any operation performed should have this as its aim. Aesthetic and other objects are of minor importance. Correct alignment is the most important factor governing success. Unless this be secured erroneous deflection of body weight upon the joints above and below the fracture results. A meticulous end-to-end union with a lateral deviation is not so successful as even a little over-riding accompanied by a good alignment. Many hundreds of fractures which violated this axiom were rebroken and the limb reconstructed. Surgeons were often able to lengthen the limb by five inches or more.

Orthopaedic surgery emphasizes the after-treatment of all these chronic cases. All joints have to be kept mobile, muscle-wasting hindered, reëducation courses attended, and all the modern advantages of physiotherapy utilized.

*Artificial Limbs.*—In the early stage of the war it was found very difficult to keep up any adequate supply of artificial limbs. All the English limb-making firms suffered from the fact that their staffs were at the front. The authorities were so firm that it was impossible to recall them, although the shortage of limbs had become appalling. An exhibition, to which all limb-makers were invited, was held at Roehampton House, and artificial limbs were sent by both English and foreign makers. The Americans, however, were alone prepared to start work with full staffs, so that the bulk of limbs supplied were of the American pattern, and were made in ever-increasing numbers on the hospital grounds. They were strong and very reliable, and, at that time, they represented all that was best and up-to-date. Later, in 1919, a parliamentary committee was constituted in England to study the question of standardizing limbs in order to lessen the cost and expedite production. After much deliberation they fixed upon certain standardized patterns suited to the more frequent sites of amputation. They were based upon the most reliable features of both the American and English types. They were manufactured in wood and leather with steel joints, and although on the whole satisfactory, complaints were often made that they were too heavy. In consequence, a standardized leg has been in course of being perfected, which combines lightness with durability, and the weight of which will not be more than four or five pounds. There can be no doubt that artificial limbs for high-up amputations had previously been far too heavy, and the introduction of a light metal or wooden splint will supply a reasonable demand.

It can be said without entering into any technical details that, as an artificial limb has to transmit the weight of the body to the ground, it should be stable, painless, and permit the patient to walk in a natural, easy manner. The weight of the body in certain cases is carried directly on to the artificial limb through the end of the stump (end-bearing). In other cases a portion only of the weight is carried through the end of the stump—the rest of the weight being distributed through other anatomical points (partial end-bearing). Sometimes it is transmitted through the bony points about the joint above the amputation—*i.e.* round the hip-joint in cases of amputation through the thigh (ischial bearing). The complete end-bearing distribution of weight is the ideal condition, but can only rarely be secured. It is best exemplified in a Symes' amputation which is performed when the front part of the foot is removed and the skin over the heel forms the flap. The skin has to be thick and the end of the bone expanded, otherwise ulceration may result.

While artificial legs have on the whole given very general satisfaction, artificial arms have been very disappointing. The leg is comparatively a simple proposition—it merely has to bear weight and perform the act of walking. The arm, on the contrary, is expected to perform diverse and complex acts. Too many arms have been merely ornamental, and have been discarded early, only to be worn for aesthetic reasons. When the war broke out only very primitive types of arms existed. They consisted of a bucket, a hinge automatically locking elbow and a dummy hand, which could be taken off and replaced by a hook or a ring. Later, certain arms were introduced which displayed great inventive ingenuity. These limbs were worked by certain movements of the body assisted by the stump. In an amputation above the elbow, for instance, the forearm could be fixed and supinated and the fingers opened and closed. They were, however, not a success owing to their weight and complexity, and the movements were not those which could prove useful in daily life. Mechanical arms of various types followed, some of which have proved useful. They are included in the class known as the "worker's arm," and consist of an apparatus where the external shape of the arm is sacrificed to utility. Various tools and other mechanical devices are attached to the end of the arm and, with training, patients are able to do very useful work. It must be admitted, however, that fully two-thirds of the men have discarded their artificial arms. Doubtless, with encouragement and better and more prolonged training, men would obtain much more satisfaction from their artificial limbs.

Temporary limbs have been employed regularly in Great Britain for the lower limbs in order to bring the leg into action at the first available moment to exercise the muscles of the stump, to avoid the evil of crutches and to allow the shrinkage of the stump to take place—an essential preliminary to the final fitting of a bucket. The bucket is usually made of plaster of Paris, moulded very accurately in order that shrinking may take place from pressure. Many excellent fibre temporary or peg legs were made by amateurs and supplied by the Red Cross Society.

The Belgians and French used temporary arms in order to keep the muscles active and the joints mobile from the time the stump healed. Schools were started in order to teach the men their possibilities and limitations. In England, owing to rapid evacuation, very little time was spent in training men to adapt their arms to their own special trades. This is perhaps one of the main reasons of failure.

One of the most interesting developments in connexion with amputations has been the so-called operation of cinematization of amputation stumps. A considerable length of muscle is preserved at the time of the amputation, and the opposing groups are separated and covered with skin. By exercise these rival groups can be trained to retract often two inches, and can thus be utilized to work an artificial hand by direct volition. Experiments are being continued and the prospects are encouraging.

*Deformities.*—The aim of the modern orthopaedic surgeon is to prevent the occurrence of deformity, and to insist upon early treatment. In the case of children there are four groups of cripples. They consist of (*a*) surgical tuberculosis; (*b*) rickets; (*c*) congenital deformities; (*d*) deformities due to injuries and infections of bone. Rickets and surgical tuberculosis account for nearly 50% of the deformities of children, while congenital deformities and infantile paralysis will account for the remaining cases. In the group of surgical tuberculosis are included spinal caries and diseases of the various joints. Amongst the rickety cases are found knock-knee, bow-legs, spinal deviations, flat-feet, deformities of hip, etc. Amongst the congenital group there are the various types of club-feet, wry-neck and allied affections.

Most of the deformities due to these various conditions may be altogether prevented, and the cases grouped under tuberculosis

and rickets should in time be eradicated, given reasonable State facilities. In the prevention of tuberculosis nothing is more important than the provision of milk free from tubercle bacilli. Until the menace of cattle affected with tubercle is removed, one of the chief origins of infection will persist. The etiology of rickets is sufficiently known to merit some organized method of control. Recent investigations with regard to vitamine have served to confirm the belief that it is largely a dietetic disease intensified by insanitary conditions. With a better education of the student as to the origin of deformities, many of the dangers of rickets would be eradicated, such as the evils of superincumbent body-weight as applied to soft bone.

Orthopaedic surgery is largely the surgery of the extremities, and the aim of the surgeon is the removal of disability. He effects this by a scientific application of the lessons to be learnt from anatomy, physiology, pathology and mechanics. In his reconstructive efforts he places the restoration of form as secondary to the restoration of function. (R. Jo.)

**ORZESZKO** (or ORSZESZKO), **ELIZA** (1842–1910), Polish novelist (*see* 20.343), died in 1910.

**OSLER, SIR WILLIAM, 1ST BART.** (1849–1919), British physician and professor of medicine, was born at Bond Head, Can., July 12 1849, the son of the Rev. F. L. Osler, a missionary. He was educated at Trinity College School, Port Hope, Trinity University, Toronto, and McGill University, Montreal, where in 1872 he took his degree of M.D. He then went to Europe and studied medicine in London, Leipzig and Vienna, afterwards returning to Canada, where he was appointed in 1874 professor of medicine at McGill University. From 1884 to 1889 Osler was professor of clinical medicine in the university of Pennsylvania, and from 1889 to 1904 professor of medicine at Johns Hopkins University; it was during this period in the United States that his international reputation was made. In 1905 he was appointed regius professor of medicine at Oxford. In this position he greatly developed the medical school at Oxford, and used all his influence towards the furtherance of advanced research. While at Oxford he served as a curator of the Bodleian library, as a delegate of the University Press, and as one of the Radcliffe trustees. He was created a baronet in 1911, and died at Oxford Dec. 29 1919. Sir William Osler was not only a great medical consultant, and one of the wisest advisers of his day on practical affairs of all sorts, but was the author of many medical works, of which the most important, *The Principles and Practice of Medicine* (1892, latest ed. 1916), has been translated into many foreign languages.

**OSTEND** (*see* 20.356).—Pop. (1914) 43,196. The extensive harbour and dock works, begun in 1900, were practically completed before the war, and 1,795 vessels of 1,155,000 aggregate tonnage entered the port in 1913. Ostend was occupied by the Germans from Oct. 15 1914 to Oct. 17 1918. The entrance channel to the harbour and to the Grand Canal connecting with Bruges and Ghent was blocked to all craft except the smallest submarines by the sinking of the "Vindictive" on the night of May 9–10 1918. During the occupation over 2,000 bombs were dropped on the town; 400 of the inhabitants were killed and several hundred injured, and 1,250 houses were either destroyed or damaged.

**OSTEOPATHY.**—According to its advocates, osteopathy is that system of the healing art which regards the structural integrity and adjustment of the mechanism of the body as the most important single factor in maintaining the organism in health, in contrast to the older systems which regard the chemical intake of the body as the most important factor. In other words, osteopathy is based on the recognition of the human body as a vital mechanism, a living machine, which, given wholesome physical and mental environment, good food, proper exercise, pure air and pure water, will be healthy, that is, will function properly, so long as all the cells and parts of that vital mechanism are in normal adjustment. Osteopathy teaches that structural derangement of the body is the predisposing cause of disease. It causes functional perversion of the vascular and nervous systems, weakening the nutritional processes and lowering the powers of resistance of the body; on the one hand, producing congestion, either general or local, active or passive; on the other, depriving tissues of an adequate blood and lymph supply. This perversion impairs the rebuilding of cells after waste due to active functioning and retards the elimination of waste products through body drainage, thus making the body unable to withstand climatic changes or unhygienic and insanitary surroundings, and offering a hospitable medium for the invasion and propagation of pathogenic germs. For example, as Dr. Still, the founder of osteopathy (*see* below), said, "A disturbed artery marks the beginning to the hour and minute when disease begins to sow its seeds of destruction in the human body. The rule of the artery must be absolute, universal and unobstructed, or disease will be the result."

If a machine is complete in its structure, and the structural relation of all its parts is perfect, it performs its function perfectly; if, however, it is not "plumb," if some of its parts are ill-adjusted, if friction is increased, it will not function properly—it will not perform its proper work. So it is with the human body. If the structural relations of the various cells, tissues and organs of this vital mechanism are in perfect harmony, and if there is an unobstructed supply of blood, lymph and nerve to all these cells and tissues, then the purposes for which these cells, tissues and organs are designed will be carried out; but if the structure is perverted in any manner the functioning also will be perverted. Integrity of mechanical structure determines the normality of functioning. That this structural perversion is the basic cause of functional disturbance or disease is a distinctive and fundamental principle of osteopathy.

Centuries old is the idea that man is a machine, and that his operations are dependent upon mechanical laws; but to Dr. A. T. Still is due the honour of recognizing the unity of the body and the law that any derangement of its mechanical structure is followed by disordered functioning or disease, and that the vital mechanism possesses the auto-protective power to restore normality of function, without pharmaceutical, chemical, electrical, or any other extraneous and artificial stimulation, as soon as complete alignment and adjustment of such derangements have been made. These structural derangements of the body are technically called "lesions." A lesion is defined as "any structural perversion which by pressure (or irritation) produces or maintains functional perversion." All the tissues of the body are subject to such perversions. They are produced by both external and internal forces. External causes are mechanical violence, such as falls, blows, strains, ill-fitting clothing and the like, and changes of temperature. Internal causes are postural influences, abuse of function, and nutritional disturbances.

A gross, frequent, palpable and easily distinguishable lesion is that of the sacro-iliac articulation. It is highly productive of functional perversions of the sciatic nerve, pelvic viscera, and the body equilibrium. Before Dr. Still's founding of osteopathy in 1874, anatomists described this as an immovable joint. He demonstrated the opposite by recognizing it as a movable joint, and correcting its derangements. This disturbance was among his first citations and teachings as an example of the osteopathic lesion. Only within the past two decades have other schools of medical practice recognized that this articulation is subject to this lesion and its resulting pathological disturbances. The more frequent, and consequently the more important, lesions are those of the bony, muscular and ligamentous tissues. Owing to their intimate mechanical relation with the nervous and vascular systems, particularly the vasomotors which control the rate of blood-flow, these tissues along the area of the spinal column are those most subject to lesions of far-reaching influence. Clinical experience also proves that a large majority of lesions are found in the spinal region. Hence the importance of maintaining the integrity of this area, both as a prophylactic and as a curative measure. And nowhere is it of such supreme importance as with children, subject as they are to the thousand-and-one stresses and strains of tumbling about from morning to night. Osteopathy teaches that nothing will contribute so much to the health of children as to see that they are examined every few months for the purpose of detecting lesions, just as they have their teeth examined by the dentist to detect lesions there. As contributive factors in the etiology of disease, osteopathy recognizes germs, abuse of function, unhygienic and insanitary surroundings, climate, etc.

Osteopathic diagnosis has but one aim, to find the cause. It includes the complete examination of the whole body and its excretions, especially the articulations and alignments of the vertebrae, ribs and pelvis. Symptoms are noted, and all chemical, microscopic, hygienic, sanitary, and other findings are studied to aid in determining the existing conditions of tissue, viscera and function. Of supreme importance, however, is the physical examination to discover existing mechanical tissue lesions. In this respect osteopathy stands alone among schools of medicine.

Osteopathic therapeutics has but one aim, to remove the cause. This may require the employment of one or more of many means. It may, and it usually does, consist in the specific manipulative removal of the lesion or structural perversion, by effecting tissue adjustments, which free the remedial anti-toxic and auto-protective resources of the organism itself; or it may consist in correcting hygienic, dietetic, environmental and psychic conditions; or in the application of operative surgery for fractures, lacerations, and the removal of abnormal growths or organs so diseased as to be danger-

ous to life; or it may be the administration of antidotes for poisons and other dangerous substances. In osteopathic therapeutics the fundamental principle is, "Find the lesion, adjust it and let it alone."

Some confusion has arisen in the minds of those unfamiliar with osteopathic practice as to the exact nature of osteopathic treatment. It consists in specific correction by manual adjustment of the several tissues involved in the lesion and no others. This corrective work should be of the highest technical order, and based upon knowledge of the tissues involved and their mechanical relations, both in health and in abnormal conditions. Some have confused it with massage. For this confusion osteopathists hold there is no justification. The principles of osteopathic treatment are as different from those of massage as are the principles of surgery. Nor does osteopathic treatment mean simply "bone-setting." Correction of bony lesions is a large and important part of the treatment, but osteopathy goes further. Whatever the cause osteopathy tries to find and remove it. If abuse of function is a contributive factor, that must be corrected. If there are insanitary surroundings, they must be removed.

Osteopathic prevention or prophylaxis comprises systemic examination for incipient lesions, and their correction before function becomes disordered; individual hygiene and right living; public education in so using the body as to avoid injury, and in sanitation.

Osteopathy teaches the self-sufficiency of the normal vital mechanism. In other than normal conditions this principle powerfully manifests itself; the hypertrophy of the heart muscle in valvular insufficiency, the healing of a wound, the recovery of the body from "light attack" diseases without any treatment, all are instances of the self-sufficiency of the body to repair pathological conditions, traumatic and otherwise. Every healed wound, every hunchback, every particle of cicatricial tissue, every adhesion, shows a successful effort of nature to heal disease, and bears further witness that only the severe and persistent impairment of the mechanism made complete repair impossible. The discovery of opsonins and antibodies and their efficacy, together with that of the active principle of the thyroid and other glands forming the internal secretions, is a mark of gradual recognition and acknowledgment of this self-sufficiency when normalized and mechanically stimulated to the maximum exhibition of its reparative and auto-protective processes. Osteopathy aims at so normalizing and stimulating the vital mechanism that it will manufacture in the necessary abundance its normal supporting and protecting chemical compounds.

Many osteopathic physicians specialize in certain branches, such as surgery, obstetrics, gynecology, defective and feeble-minded children, mental and nervous diseases, conditions involving the lymphatics, and eye, ear, nose and throat affections. The results secured through osteopathy with defective and under-developed children are such that judges in juvenile courts in many cities have designated osteopathic physicians to give these unfortunates professional care in a sincere effort to reclaim them before committing them to an institution. The success attending the efforts of those physicians specializing in nervous and mental diseases has been so marked that several sanatoria have been established for the exclusive care of persons so afflicted. The field of the eye, ear, nose and throat has, however, attracted by far the largest number of osteopathists who practise as specialists.

The special "technique" employed, variously known as "finger surgery," "finger technique," and "finger treatment," first developed and first given to the profession by an osteopathic physician in 1911, has been described as a system of digital manipulations of these regions whereby the physician adjusts the bony, ligamentous, nervous and muscular lesions, and breaks up any adhesions and masses of lymphoid tissue that interfere with drainage and with ventilation in any of the apertures, and by such technique restores the normal functional activity of the parts. This method was first used in catarrhal deafness, but is now employed in a number of other pathological conditions of these organs. Catarrhal deafness, hay fever and tonsillitis are the diseases most amenable to this treatment.

Osteopathic practitioners soon felt the need of institutional care for certain kinds of both acute and chronic pathological conditions. This need was all the more important on account of their being denied the opportunity of caring for their patients in the existing institutions controlled by the dominant school of therapy. Therefore, within recent years a number of general hospitals and numerous sanatoria under control of the osteopathic profession have been established.

Much excellent experimental research has been done by members of the profession under the direction of the A. T. Still Research Institute at Chicago. The work is chiefly along the line of osteopathic fundamentals, such as the production of lesions; the study of perverted function and the pathological conditions resulting therefrom; the correction of the produced lesions, and the study of the results following such corrections. These experiments, through clinical observations and post-mortem dissections on various animals, have demonstrated, among other things, that when a spinal lesion is produced, pathological changes in the tissues of the various viscera involved result (for example in that of the stomach, kidney, liver, intestines, pancreas and thyroid gland), and that abnormal functional digital those viscera also results (for example diarrhoea, constipation, hepatitis, glycosuria, increased susceptibility to infection, and formation of goitre). The experiments have further demonstrated that the correction of the produced lesion is followed by a return to normal functioning. The produced lesions also showed profound pathological changes in the vascular mechanism of the posterior ganglion, the cells of the grey matter of the cord, and in the sympathetic ganglia, all of which affected their functioning. The experimental and clinical use of radiography in research and practice has demonstrated the existence of bony lesions and their non-existence following osteopathic adjustment.

The founder of osteopathy, Dr. Andrew Taylor Still, was born in Virginia Aug. 6 1827, and died at his home in Kirksville, Mo., Dec. 12 1917. He was a practising allopathic physician at the beginning of the American Civil War, served as a Union officer during that struggle, and at the close of the war returned to his home in Kansas and resumed the practice of his profession. Gradually his confidence in the efficacy of drugs as a means of healing weakened, and his faith in the inherent curative power of the body strengthened, until June 22 1874, when he publicly announced that he would henceforth discard the use of drugs as a curative measure and would dedicate the remainder of his life to aiding nature in the alleviation of disease by the mechanical readjustment of the disordered body. The American School of Osteopathy was opened at Kirksville, Mo., in 1892. There were in 1921 over 7,000 graduate practitioners of osteopathy in all parts of the world.

In addition to the school at Kirksville, there were in 1921 six others in the United States devoted to the teaching of osteopathy: The Philadelphia College of Osteopathy at Philadelphia; The Des Moines Still College of Osteopathy, Des Moines, Ia.; The College of Osteopathic Physicians and Surgeons, Los Angeles, Calif.; The Chicago College of Osteopathy, Chicago; The Massachusetts College of Osteopathy, Boston; and The Kansas City College of Osteopathy and Surgery, Kansas City, Mo. The student enrolment is second only to that of the allopathic colleges. The matriculant must have had at least a four-year high-school course or its equivalent. The curricula of the osteopathic colleges embrace all the subjects taught in other medical schools, except "Materia Medica," in place of which there is included "Principles and Practice of Osteopathy" and "Osteopathic Therapeutics." The course of study is four years of at least eight months each spent in actual attendance in one of the above recognized colleges. Osteopathy was by 1921 recognized and regulated by law in 47 states of the United States. The one remaining state, through court decisions, makes its practice legal. There is an international organization, the American Osteopathic Assn., having some 3,200 active members; an osteopathic association in each state in the Union; associations in Canada; the New England Osteopathic Assn., the Western Osteopathic Assn., the Eastern Osteopathic Assn., the South Atlantic States Osteopathic Assn, Osteopathic Women's National Assn., a British osteopathic association, the Academy of Osteopathic Clinical Research, and the American Society of Ophthalmology and Oto-Laryngology. There are 10 or 12 magazines and periodicals published by the profession.

(G. W. Rr.)

**OTTAWA** (*see* 20.369), the capital of the Dominion of Canada, had with its suburbs a pop. of 135,154 in 1920, according to a local census. The pop. in 1911 was 87,062. It is probable that the 1920 figures were greatly exceeded during the years of the World War, when a large influx to the city was occasioned by the Government's war organization. The Dominion Parliament buildings were almost completely destroyed by fire on Feb. 3 1916. The magnificent library and the senate house fortunately escaped destruction. Reconstruction was undertaken at once through a special committee representative of both Houses of Parliament, which were then in session. John A. Pearson of Toronto and J. O. Marchand of Montreal were the architects. The corner-stone of the new building was laid in September 1916, by the Duke of Connaught, then Governor-General, the stone being the same as that laid by his brother, the late King Edward VII., when he visited Canada as Prince of Wales in 1860. The corner-stone of the new tower was laid by King Edward's grandson, Edward, Prince of Wales, in 1919. The main front of the new Parliament buildings is 470 feet long and nearly 100 feet high, the length being the same as that of the former buildings but the height double as great. The main tower of the new buildings, still under construction in 1921, was to be 300 feet high, about 100 feet higher than the old tower.

Other buildings erected since 1911 include the Grand Trunk Union Station, on the east bank of the Rideau Canal and on the south side of Rideau Street—a large structure replacing a previous inadequate building—and the Chateau Laurier in Major's Hill Park

facing the Parliament buildings. The Chateau Laurier is a large and luxurious hotel owned and operated by the Grand Trunk Railway system, by whom it was built at a cost of $2,500,000. It is connected with the railway station by a subway under Rideau Street. Under the Ontario provincial housing scheme a colony of new houses for the use of Ottawa's civil servants was in course of erection close to Rockcliffe Park in 1921.

In 1920 Ottawa had 388 industrial establishments of various kinds—iron works and foundries and large factories for the production of paper, cardboard, tents and awnings and cement—giving employment to 11,873 persons and paying out in annual wages $8,938,170. It has one of the largest individual lumber factories in the British Empire. The district output of lumber in 1918 was 350,000,000 feet, board measure. In 1921 Ottawa was consuming about 54,000 H.P. of electric energy, most of which was generated at the Chaudière Falls. Nearly 200,000 H.P. available for commercial purposes was still undeveloped within a radius of 30 m. of the city.

**OTTOMAN EMPIRE** (*see* 27.426).—The Turkish Revolution of 1908 was thought, at the time, to promise an era of genuine reformation and revival for the Ottoman Empire; a few years showed that it had opened, instead, the final brief period of that empire's existence. Long declining, long owing its continuance to the jealousies and conflicting policies of the great European Powers, the Ottoman Empire may be said to have ended, as the result of defeat in war, when its delegates signed the Treaty of Sèvres on Aug. 10 1920. From that treaty emerged a Turkish State with every attribute of empire gone.

The first constitutional Government which came into power in Turkey after the revolution speedily found itself opposed by the "Young Turk" Committee of Union and Progress—the same occult body which had organized and carried through the revolution. The hope had been general that the Committee would cease their activities when once parliamentary government was established; but the hope remained unfulfilled. The Committee transferred their attention from the Sultan Abdul Hamid to the Ottoman Parliament—which assembled on Dec. 17 1908—as the new means to power, and continued as active as ever. Within a few weeks they had procured the downfall of Kiamil Pasha, the first Grand Vizier of the constitutional period.

The Committee had, in fact, a definite policy before them for execution; a policy by no means in harmony with the professions of liberty and equality for all Ottoman subjects upon which the revolution had been accomplished. Briefly stated this policy was the complete "Turkification" of the empire. Non-Turkish ethnical elements—Albanians, Macedonians, Armenians, Greeks, Arabs, Kurds, Druses—were to be moulded as far as possible into uniformity with the dominant Turkish element. Racial and national ideals, characteristics, laws and languages of these subject peoples were to be suppressed, by force if necessary, and an Ottoman population created which, outwardly at least, should be homogeneous within the empire's wide confines. Nor did the Turkish Moslem population escape the reforming purpose of the Committee. Taking a detached view of Turkish civilization, even of the faith of Islam itself, for the two are inseparable—the Committee saw much wanting, much existing that was cumbersome and useless, much that provided a fatal handicap to the progress of the Ottoman State.

For the good of the Turkish race and the ultimate Ottoman State the Committee intended reformation in these directions as well. But various of the changes proposed touched exceedingly delicate matters, going to the deepest foundations of Turkish belief and prejudice: so much so that some of the desired reforms could not be openly advocated as yet. The reforms proposed included the adoption of European time, the European calendar, and the Latin alphabet; the abolition of veiling of women—as a practice of far-reaching, injurious influence upon the race; the abolition of the annual, month-long fast of Ramazan, and of the Feasts of Bairam. In other directions, too, the teachings of Mahomet were to be judiciously revised, on the principle that the Prophet himself would never have allowed observance of any of his precepts to put his followers at a permanent disadvantage in competition with infidels. That many years, perhaps two generations, must elapse before the more serious of these changes would be accepted by Turkish Moslems was well understood. But the "Turkification" of non-Turkish populations was on another footing. The sooner it was begun and the more thorough were the measures adopted, the sooner would its advantages be reaped. Reorganization of the army and navy was regarded as imperative, not only against external possibilities, but for execution of the policy of "Turkification." Financial reform and reorganization of the customs service were found equally necessary, if only to provide means for the increased cost of the army and navy. These matters therefore were taken in hand. Djavid Bey, Minister of Finance, called a French adviser to his assistance; a British adviser, Mr. R. F. Crawford, was engaged to reorganize the customs; a number of German officers, selected by General von der Goltz, were brought in to reform the army; and the work of restoring the navy to efficiency was entrusted to a British adviser, Rear-Admiral Gamble, and a small British staff.

Though the Committee of Union and Progress took no open part in governing the country, and remained an unseen mysterious power, they had their nominees in the Ministry, and at the beginning of 1909 could already influence the policy of the Government. Opposition to the Committee became, therefore, opposition to the Government as well. The revolution had given birth to a strong nationalistic spirit in Turkish Moslems and a desire to restore the empire to something of its former power, but had not diminished their religious zeal. Devout Moslems became alarmed at the tendencies of the Committee; at the free-thinking professions of members and their general rejection of the Prophet; still more at the innovations advocated in Turkish customs and in the Mahommedan faith. The Mahommedan Union was formed to oppose the Committee and its dangerous projects, and declaring that Islam was in danger, the Union became active early in April 1909.

The Sultan Abdul Hamid has been charged with being the chief instigator of the counter-revolution of that month; it is more probable that he did nothing except oppose it. The counter-revolution was chiefly the outcome of religious zeal played upon by the Mahommedan Union. The troops in the capital were won over (the same troops who had effected the revolution of the previous year), and on April 12 they demanded that the constitution should be subject to Mahommedan sacred law, and great demonstrations, attended by fighting, taking place against the Government. The Grand Vizier resigned, leading members of the Committee fled from Constantinople and the Sultan pardoned the troops who had taken part in the movement. But the counter-revolution had no organized strength behind it. The Committee retained the support of the two army corps stationed at Salonika and Adrianople; and from these garrisons a force of 20,000 men was dispatched against Constantinople. It occupied the city on April 24, and crushed the rising after much street fighting.

The Committee had ever regarded the Sultan Abdul Hamid with deep suspicion, which the counter-revolution was held to have justified. The counter-revolution provided, therefore, a favourable excuse for removing him from power. He was deposed on April 27, and sent to Salonika for internment and safe-keeping; and his successor, as Sultan Murad V., was proclaimed the same day. After the prompt suppression of this rebellion, the Committee became sovereign in the direction of Ottoman affairs. It had, however, learnt the danger of outraging the national and religious susceptibilities of Turkish Moslems. For the future they showed more deference to these sentiments, and, recognizing the forces behind them, gave more and more prominence to Pan-Islamism as a feature of the Committee's policy. Soon after the events of April, Talaat Bey, destined to fame as a sinister figure largely responsible for the downfall of the Ottoman Empire, became Minister of the Interior as one of the Committee's nominees in the Government. After the Committee had suppressed the counter-revolution, and was firmly seated in the saddle, events moved by regular and rapid steps to the end of the empire.

During the first two weeks of April, while Constantinople was in the throes of revolution, serious events were taking place in Adana, the prosperous capital of the Cilician plain. Racial hatred between Turks and Armenians there came to a head on April 9 in the so-called "Adana Massacres." These soon ex-

tended over the whole of Cilicia and, before they had ceased, involved the death of some 20,000 Armenians and a lesser number of Moslems. Both the Government and the Sultan Abdul Hamid have been charged with responsibility for the outbreak; but instigation to the deed, though not perhaps directly from the Government, appears to have come from the Committee. It well may be that these massacres were, in fact, an abrupt and premature step in the policy of "Turkification," which the Government had in view.

In its various forms, this policy gave rise to the chief internal preoccupations of the Government during the years 1909–12. In 1909, as part of the same policy, a law was passed imposing compulsory military service on all Christian subjects of the empire for the first time. In the same years, stern military suppression accompanied by much bloodshed was applied in Albania and Macedonia; taxation and conscription were enforced, the national schools closed, and Turkish decreed as the official language. In Syria too, Turkish was made the official language, and Arabic forbidden in the schools.

A local quarrel in the Hawran was seized as a pretext in 1910 for dispatching thither some 30,000 men, with artillery, to crush the Druses. The operations, however, did not result entirely to the advantage of the Turks, who suffered at least one serious reverse, and a compromise followed under which the Druses accepted conscription for the Ottoman army.

South-western Arabia, where the Imam Iahya of the Iemen and the Idrisi of Asir rebelled at the end of 1910, was another region marked down for "Turkification." Military operations to this end were undertaken on a large scale during 1911; but again without definite success. Some 50,000 Turkish troops were employed, but, though able to relieve beleaguered Turkish garrisons, they could not penetrate the mountainous region forming the Arab stronghold and were unable to establish Turkish domination.

The Ottoman Government took these experiences to heart. They recognized that the "Turkification" of distant provinces containing no Turkish population was a task beyond their power, and the policy was therefore relaxed in certain districts. In the Iemen, in fact, a measure of local independence was granted to the Imam Iahya, though not to the Idrisi of Asir. "Turkification" was now reserved for Turkey in Europe and for the great compact territory of Asia Minor, the fastness of the Turkish race, by systematic and thorough processes, it being intended to make this wide area Turkish in population and spirit beyond question or doubt. For the time being, however, it seemed that the empire might hope for a period of comparative freedom from internal disturbance.

But external difficulties now arose. Italy had long shown designs on Tripoli, the remaining African province of the Ottoman Empire. During 1911 various matters had created friction between the two countries and caused the exchange of bitter articles in the press, but war had appeared unlikely. On Sept. 29 1911, however, the Italian Government presented an ultimatum stating that, Turkish obstruction and hostility to Italian interests having become so great, the occupation of Tripoli had been decided upon. The ultimatum required Turkish acquiescence to this course within twenty-four hours. The Turkish reply did not accept the occupation, and Italy declared war on Sept. 30. The Turkish garrison was small; it could not be reinforced owing to Italian command of the sea; the Turkish defence in Tripoli therefore had to rely chiefly upon Arab forces locally raised. Italian troops landed on Oct. 12 and the bombardment and capture of towns along the coast began. No serious operations were attempted far inland; and though severe fighting took place effective Italian occupation never extended far from the sea. Italian warships blockaded and bombarded Turkish ports on the Red Sea coast of Arabia and supplied arms and munitions to the Idrisi of Asir, to the great advantage of that ruler. Various Turkish islands in the Aegean Sea, including Rhodes, were occupied by Italian troops in the spring of 1912. A naval demonstration against the Dardanelles was also made. This affair prompted the Ottoman Government to close the Dardanelles and Bosporus against all shipping, a course which caused immense loss and inconvenience to neutral Powers and produced such vigorous protest, particularly from Russia, that the straits were reopened in May. The war, hopeless from the first, continued for another six months, marked only by unavailing efforts in Tripoli by Enver Bey—the well-known member of the Committee of Union and Progress—at the head of Arab irregulars. But difficulties of finance, the impossibility of undertaking effective operations against Italy, and signs of impending trouble in the Balkans at length compelled the Ottoman Government to peace. Under the Treaty of Ouchy, signed on Oct. 18 1912, Tripoli, the last Ottoman territory in Africa, passed into Italian possession. Rhodes and other Turkish islands were retained by Italy for the time being.

Balkan unrest had shown itself in unusually ominous form as early as the beginning of May 1912. Following the general elections in April for the Ottoman Chamber, in which the Committee of Union and Progress had exhausted every method of corruption and violence to secure the return of their candidates, 30,000 Albanian clansmen, exasperated by "Turkification" and repression, mustered in organised rebellion. Their purpose was the overthrow of Committee Government, to which end they demanded new elections. The Government temporized and took inadequate military measures; meanwhile a rebellion grew, and Turkish and Christian hatred became more and more inflamed. At the close of July, the massacre of Christians at Kotchana deeply excited Balkan opinion. It was followed by a similar massacre of Christians at Berana, and events now moved rapidly toward war. The Turkish Government saw nothing for it but compliance with Albanian demands, at least in form; and on Aug. 6, to the rage of the Committee, their hardly won majority vanished in the dissolution of the Chamber by imperial decree. As a further concession to the insurgents, reforms on the widest scale were promised; but their application required time, even if the good faith of the Government could be trusted.

Matters had gone too far, however, for any Turkish concessions to avail. The Balkan States—Bulgaria, Serbia, Greece and Montenegro—regarded themselves as the dispossessed owners of Ottoman territory in Europe. They deemed that now, with organized rebellion afoot in the Turkish Balkans, was the opportunity to recover Macedonia and Thrace for division among themselves. They judged, further, that should their attempt by any chance miscarry, the Great Powers, more particularly Russia, protector of the Slav peoples, would not allow them to be crushed, or their present territories to be diminished. For the execution of their purpose, Bulgaria, Serbia, Greece and Montenegro had already formed an alliance. Bulgaria began her mobilization at the end of September, followed immediately by her allies; Turkey ordered mobilization on Oct. 1; by Oct. 18 1912 the four Balkan States were at war with the Ottoman Empire.

When war broke out the Ottoman forces in Europe numbered less than 250,000 men, dispersed over Macedonia and Thrace; they were thus at great numerical disadvantage. The Anatolian troops, ever the bulk of Ottoman armed strength, had to be conveyed great distances by inadequate means of transportation. The full strength of the empire could not be exerted in Europe until months had elapsed; and the outcome of the war was decided in the first two weeks.

The war was fought in two chief theatres of operations—the less important in Macedonia, against the Serbian, Greek and Montenegrin armies, assisted by two Bulgarian divisions; the more important in Eastern Thrace against the Bulgarians, later assisted by a considerable Serbian force.

In the Macedonian area the Turks were defeated by the Serbian army at Kumanova on Oct. 24–25, and lost Uskub in consequence. Another Serbian force, uniting with Montenegrins, had occupied northern Albania the end of October. The main Turkish army retreated on Monastir, where, on Nov. 14–18, it was again defeated by the Serbians, who outnumbered them in the proportion of 5 to 2.

The Greeks, meanwhile, who crossed the frontier with six divisions on Oct. 18, had made Salonika their objective.

They easily defeated the comparatively weak Turkish forces opposing them, and arrived before the city on Nov. 8, anxious to forestall a Bulgarian column aiming at the same objective. The Bulgarians, who took Serres on Nov. 5, reached Salonika at about the same time as their rival; but the Turkish commander chose to capitulate to the Greeks, who occupied the city the next day. Within four weeks the Ottoman Empire had lost Macedonia and Albania except the fortress and district of Yanina whose garrison as yet lay outside the area of operations.

These were rapid and remarkable triumphs, but they did not affect decisively the outcome of the war; they took from Turkey two outlying provinces; they did not strike at the heart of Turkish resistance. The weight of Turkish resistance lay in Eastern Thrace, concentrated there for the defence of the capital and the straits. Turkish reinforcements could not reach Macedonia by sea as fast as rail and steamer could bring them. They were poured into Eastern Thrace from Anatolia. The heavy and decisive operations of the war were carried out by the Bulgarian army.

The main Bulgarian advance was made south-eastward through Eastern Thrace. During Oct. 21–25 the Turkish armies commanded by Abdulla Pasha were driven back in confusion and retired to positions passing through Bunar Hissar and Lule Burgas to the railway. The fortress of Adrianople, containing a large Turkish garrison, was thus isolated and left to Bulgarian investment. Between Oct. 29 and Nov. 3 the issue of the war was decided at the great battle of Lule Burgas, in which the Turkish army was heavily defeated, and retreated in disorder to the Chatalja lines, in front of Constantinople. Abdulla Pasha was superseded, and the defence of the capital entrusted to Nazim Pasha, at the time Minister of War in the Turkish Cabinet.

A great attack by the Bulgarian army on this last defence of the capital took place on Nov. 17–18. It was pushed with determination, but achieved no success, and no further attempt was made. Bulgarian losses were great, and the army ravaged by cholera; on Dec. 2 an armistice was concluded which remained in force until Jan. 1 1913. During this period the Turkish Government, with Kiamil Pasha as Grand Vizier, was overthrown by a *coup d'état;* and Nazim Pasha, the commander-in-chief, who like Kiamil had been in favour of peace, was assassinated in Constantinople. In consequence of these events, originating with the Committee of Union and Progress, hostilities were recommenced at the beginning of February. Subsequent Bulgarian operations were confined to resisting Turkish attempts to advance from Chatalja; to the occupation of Thrace down to the Sea of Marmora; to resisting an attack on the Bulgar lines across the isthmus of the Gallipoli Peninsula; and to the capture of Adrianople. This great fortress was taken by assault, in which Serbian troops bore a part, during the last days of March, and a second armistice was arranged soon afterwards.

To these armistices Greece did not subscribe. She continued naval operations and occupied all Turkish islands not under the Italian flag; and on Jan. 17 1913 a Greek squadron roughly handled the Turkish fleet in serious naval encounter.

Peace negotiations had been in progress in London since Dec. 1912, but made little headway owing to Turkish obstinacy. The hope of advancing from Chatalja and relieving Adrianople—of in fact changing the whole course of the war—was sufficient to prevent all but small concessions on the part of the Turkish Government. The fall of Adrianople on March 26 ended these unrealities; and on May 30 1913 the Ottoman delegates signed the Treaty of London. The Treaty provided for the cession by Turkey to the allied Balkan sovereigns of all European Turkey west of the line Enos–Midia, but excluding Albania; for the delimitation of Albania's frontiers by the Great Powers; for the cession of Crete to Greece; and for the destination of other Turkish islands being left to the same Powers.

Within a month of the signature of the treaty, the second Balkan War broke out between Bulgaria and her allies over the division of territory wrested from Turkey. The Bulgarian armies were on the Greek and Serbian frontiers; the force left in Thrace was weak, and the Turkish Government saw their opportunity. Two months after the same Government had signed away their European provinces, Enver Bey at the head of a Turkish army overran Eastern Thrace and reëntered Adrianople almost unopposed. Bulgaria herself was helpless; the Powers would not assist her; her late allies—now her enemies—were not opposed to the Turkish aggression; and in the end Bulgaria executed a treaty restoring the province to the Ottoman Empire. For the Committee of Union and Progress it was a triumph beyond expectation. They were again the power behind the Government and now had not only justified but confirmed their position.

It is necessary now to glance at the growth of German influence in the Ottoman Empire as being closely connected with the Turkish downfall. A definite German policy of penetration had been at work for many years. German commercial undertakings had been encouraged and assisted by the German Government to acquire immense and valuable interests within Ottoman domains; among them the construction and working of the great line of railway designed to connect Constantinople with Syria, Arabia and Bagdad. In fact the economic development of Asia Minor, a backward but richly endowed land, great in area as Germany herself, had been secured for German enterprise when the first Balkan War intervened. Much more than commercial advantage lay behind Germany's aims; political advantages of incalculable importance were also in view. In the great vision of world domination which had gradually unfolded itself before German Imperialists, the high-road to be followed ran through Constantinople and Asia Minor—thence the East and the chief waterway to it, the Suez Canal, would come within reach. In prosecution of these political designs, Turkish officers were ever welcomed in the German army. They were attached to it in numbers; they returned imbued with professional admiration for German military organization and science; with a conviction of German power; they became the conscious or unconscious agents of German policy. The bond thus established caused German advice and assistance to be sought in reorganizing the Ottoman army. It led also to relations between Germany and the Committee of Union and Progress. And because each found that much might be got from the other, Germany and the Committee worked more and more in alliance. German influence eventually became so great that when the time came, the Committee leaders were willing and able to bring their country into the World War on the side of Germany.

To complete German political preparations in the Near East, and to make her Turkish Alliance effective, it was necessary to secure the support of Bulgaria. This country lay across and completely barred the German route to Constantinople. The prospect of revenge upon her enemies of the Second Balkan War—Serbia, Greece and Rumania—and of attaining her large territorial ambitions at their expense, proved sufficient, after prudent hesitation, to attract Bulgaria to the side of Germany.

After hostilities broke out in Europe in Aug. 1914, Turkish public opinion, such as it was, desired nothing so much as the avoidance of war by the empire. That was the supreme desire, but no effective means of enforcing it existed. The Committee was all-powerful in the Government, and a small group of leaders—Enver, Talaat, Djemal Pasha and others, supported by the presence at Constantinople of two German warships, the "Goeben" and "Breslau," were able to commit the country to hostilities, by the bombardment of Russian Black Sea ports by these vessels under the Turkish flag. At the beginning of Nov. 1914, Great Britain, Russia and France had all declared war on the Ottoman Empire.

In justification of their action, and to enlist the support of the Turkish people, the Government made much of the facts that the war was against Russia, the traditional and inexorable enemy of the empire, and that Great Britain and France were in alliance with Russia. The war policy of the Government was declared to be primarily the protection of Islam, particularly Turkish Islam, against the hostile and dangerously subversive policy of Great Britain. The recovery of lost Ottoman territory, the furthering of Pan-Islamism, and the freeing of the empire from all exasperating fetters of European control, were given as

additional and important purposes in view. In support of the policy, and to emphasize the religious character of Ottoman war aims, a Jihad or Holy War was proclaimed by the Sultan as Caliph of Islam.

Turkish entry into the war on the side of Germany profoundly affected the course of the war. Coupled with similar action on the part of Bulgaria it isolated Russia and Rumania from the Western Powers, and was a potent influence in producing the collapse of the Russian Empire. It compelled the Allies to gigantic military efforts far from their own territory and bases, as the only means of countering the advantages Germany gained from Turkish and Bulgarian support. It prevented food supplies from southern Russia reaching the peoples of western Europe who needed them. It came within a narrow margin of setting the Mahommedan world ablaze against Great Britain and France—on which Germany had counted—a catastrophe averted by the accident that the Sherif of Mecca opposed the Jihad and divided Islam. Participation in the war involved the Ottoman Empire in hostilities on every front of her territory; it was the penalty of her action and her geographical situation.

During the spring and summer of 1915 a British and French Expeditionary Force attacked the Dardanelles. It was recognized that in Constantinople lay the heart of the whole Eastern theatre, and that if the Straits were forced and the Ottoman capital occupied, the war in Europe itself would be greatly shortened. The campaign failed directly to achieve its purpose, but nevertheless, the Turkish regular army, irreplaceable in so far as it had been brought to a high state of efficiency by German reorganization and training, was destroyed during the operations. Foiled at the Dardanelles the Allies next attempted to attain their ends by a much greater expedition to Salonika. Its aim was to sever German communications with Constantinople by knocking Bulgaria out of the war. The Salonika area became at last the third chief zone of Allied military effort, but no great success attended the expedition until near the close of 1918. In these operations no Turkish troops took part, but in 1916 Turkish divisions had to fight in the great invasion of Rumania.

With the empire at war and the Committee in power, the Turkish Government resolved to execute their cherished scheme for the complete "Turkification" of Asia Minor. Under Talaat Bey, the Minister of the Interior, the process was begun in ruthless fashion during the spring of 1915. Greek elements of the population were deported in tens of thousands from coastal regions where they had become unduly numerous, and taken into the interior; and many were killed. But "Turkification" was aimed chiefly against the Armenians, who were to be exterminated. During 1915–6 organized massacres and deportations were carried out systematically, to the extent of almost uprooting the Armenian race from Asia Minor. Hundreds of thousands were slaughtered; hundreds of thousands set marching for Syria and Mesopotamia perished on the way by hardship, disease, starvation; those who escaped became fugitives; from first to last at least three-quarters of a million Armenians perished in Asia Minor in a population of less than two millions. Only in the Turkish provinces bordering on Trans-Caucasia did massacre and deportation fail. In these districts the Armenian inhabitants were able to escape into Russian territory or were saved by the advance of Russian armies.

In this Turko-Russian frontier the Turkish Higher Command had expected to do the greater part of their campaigning. It was one of the empire's historical fronts; beyond it lay the traditional Russian enemy; on the hither side was the Ottoman fortress of Erzerum, the greatest place of arms in Asia Minor. In this mountainous region, between the Black Sea and the Persian frontier, the war was carried on with fluctuating fortune. Erzerum was captured by the Russians on Feb. 16 1916; and the Russian armies advanced westward till they held 30,000 sq. m. of Ottoman territory. On the collapse of the Russian Empire in 1917 the Turks were able to recover ground; and under the Treaty of Brest Litovsk between Germany and Russia, signed on March 3 1918, Turkey's claims to the provinces she had lost to Russia in 1878 were recognized. Turkish troops occupied these provinces of Ardahan and Kars during 1918, and penetrated still farther into Trans-Caucasia.

In Mesopotamia from 1915 onward the Ottoman Empire had been faced by serious British military operations, here, too, with various changes of fortune. But eventually the British captured Bagdad and overran Mesopotamia from the Persian Gulf to the borders of Syria. At the end of 1918 a Turkish army from Syria made an attempt to reach the Suez Canal and cut British sea communications with the East. A battle was fought on the Canal banks, and some Turkish detachments succeeded in launching pontoons on the Canal itself. But the attack failed; subsequent attempts were defeated far from the waterway, and at the end of 1917 the British had reached southern Palestine, and the Turkish army was on the defensive, with other matters than the Canal to engage its attention.

Much had been hoped for from Arabia by Turko-German leaders, both as giving opportunities for offensive operations against the British line of communications passing along the Red Sea, and as the seat of a great spiritual influence in Islam to be exerted against the Allied Powers. In Arabia were the Holy Cities of Mecca and Medina, governed by the Sherif of Mecca, a dignitary and ruler of great influence in the Mahammedan world. He had already declined to support the Jihad. In June 1916 he rose in rebellion against the "Young Turk" or "Committee Government" of Turkey, and obtained British support. From this time onward, Arabia, instead of being a possible source of strength to the Ottoman Empire, became the theatre of hostile operations which presently extended northward to southern Palestine and endangered the left flank of the Turkish army threatening Egypt. By the end of 1917 the British under Lord Allenby had reached and occupied Jerusalem. And in the brilliant campaign during the autumn of 1918 they destroyed or captured nearly the whole Turko-German army in Syria, and only stayed their advance N. of Aleppo. This campaign ended all Ottoman resistance. The Armistice of Mudros, signed on Oct. 30 1918, terminated hostilities between the Allied Powers and Turkey, gave the Allies control of Constantinople and the Straits, and ensured the evacuation of Trans-Caucasia by Turkish troops. It marked, too, the end of "Young Turk" Government in Constantinople, for the leading members of the Committee of Union and Progress fled the country. The Armistice between the Allies and Germany, signed on Nov. 11 following, confirmed the final triumph of the Allied Powers in all the various theatres of war.

The remaining history of the Ottoman Empire up to Dec. 1921 has chiefly to do with the deliberations of the Allied Conference in determining the conditions of peace. The treaty embodying the terms of the Allied Powers was eventually signed at Sèvres by the Ottoman delegates on Aug. 10 1920. The territorial provisions of the Treaty reduced the empire to a nation little larger than Spain. Eastern Thrace and a considerable territory around Smyrna were assigned to Greece. Mesopotamia, Syria, Palestine, and Turkish Arabia were likewise forfeited; and the southern frontier of Turkey became a line running roughly E. and W. from the Persian frontier to the head of the Gulf of Alexandretta. The Dardanelles, Bosporus, the Sea of Marmora, and the adjoining coastal areas, both in Europe and Asia, were demilitarized, and, to the extent necessary to ensure the freedom of the Straits, were placed under the control of an International Commission. Constantinople, however, remained the Turkish capital. The frontier of the Armenian state, so far as the state should include Turkish territory, was referred to the delimitation of President Wilson, whose decision the Treaty bound the Turks to accept. The [illegible] roughly laid down gave some 30,000 sq. m. of eastern Asia Minor to Armenia, including the Black Sea port of Trebizond.

Turkish history after the Treaty of Sèvres was signed belongs to Nationalist Turkey, the [illegible] formed by Turkish Nationalists, with its capital at Angora, to resist the execution of the Treaty. (*See* TURKEY, NATIONALIST.) (W. J. C.*)

**OWEN, EDMUND** (1847–1915), English surgeon, was born at Hinchingfield, Essex, April 7 1847. He received his medical

education at King's College, London, and St. Mary's hospital, taking his surgical and medical degrees in 1868 and 1872, and afterwards studied in Paris. He was consulting surgeon to many institutions, including the French hospital, St. Mary's hospital, and the Hospital for Sick Children, Great Ormond St., and wrote many important works, among them being *The Surgical Diseases of Children* (1885, 3rd ed. 1897); *Cleft Palate and Hare Lip* (1904, new ed. 1914); *Appendicitis* (1914), besides the surgical articles in the *E.B.* He also gave the Bradshaw lecture on cancer in 1906. He died in London July 23 1915.

**OXFORD** (*see* 20.405).—The population of the city increased from 53,048 in 1911 to 57,052 in 1921. Apart from the disappearance of the horse-trams in 1914, in favour of motor-buses, and the starting of the "Garden Suburb" in the Cowley Road in 1921, the municipal progress for the decade, as apart from the university, has few features of special interest.

*The University.*—During the World War 14,561 Oxford men served in the British military and naval forces, this total including prospective members of colleges who fell in the war, and also those who joined the university after the war, in which 2,660 Oxford men lost their lives. This was the number "commemorated" at the university memorial service at St. Mary's in June 1919.

The most important service rendered by the university was in the supply of officers for the new armies. The O.T.C. in Oxford was a flourishing body before the war, and, thanks mainly to it, nearly 2,000 Oxford men had received commissions by the end of Sept. 1914. After that date Oxford became one of the main training grounds for officers: all the colleges but one gave up the larger part of their space for military purposes, especially for the training of cadets, of whom there were, for the last three years of the war, nearly 2,000[1] always in Oxford. The examination schools in the High Street were ready as a hospital in the second week in Aug. 1914, and remained in military occupation till the summer of 1919.

As a natural result of the war the numbers of the university fell rapidly: there were 3,097 in residence in Jan. 1914, 1,087 at the same period in 1915, 550 in 1916, 460 in 1917, 369 in 1918. With the Armistice the tide turned, and there were 1,357 men up in Jan. 1919. For Oct. 1920 the university calendar gave the names of 5,002 men and 687 women as undergraduates; the first figure probably indicates an actual number of nearly 4,500 men in residence. As the university did not elect to its scholarships and prizes during the war, and also did not fill up the professorships that fell vacant, a considerable fund (about £50,000) was accumulated, in spite of the falling-off in the ordinary revenue. This fund was also built up in part by the voluntary gifts of members of the university.

In 1920 women students were admitted to full membership of the university. It had long been generally felt that the two old British universities must soon follow the example of all the modern ones, in admitting women to equal privileges with men. No doubt, however, this concession was hastened by the success of women's work in the war.

Another old burning question was settled by the passing of a statute in 1920 admitting to the Oxford theological degree scholars who are not members of the Church of England.

Important changes have also been made of a less revolutionary nature in the university constitution and its educational facilities. The Hebdomadal Council is no longer evenly divided among heads of colleges, professors and ordinary M.A.'s; three of the seats previously reserved for heads are now thrown open. A further change affecting the Hebdomadal Council is the institution (in 1913) of a general Board of the Faculties, which has power of initiating legislation on all subjects connected with the studies of the university. Oxford finance, too, has been provided with more efficient machinery, first by setting up (1912) an outside finance board to advise the university Chest, and then in 1920 by the reconstitution of the Chest itself. In the development of the organization for research, the tentative step taken in 1895 by the setting-up of the degrees of B.Litt. and B.Sc. has been followed by the creation (1917) of a Ph.D. degree, involving two to three years of independent work, for graduates of Oxford or of other universities.

A new engineering laboratory was opened in 1912, and a new chemical laboratory in 1915; this last has been munificently endowed by Mr. Dyson Perrin's gift of £25,000. Several colleges have extended their boundaries by taking in adjacent houses, and the Oxford Union Society opened its new block in 1913. Another addition to university buildings is Barnett House, opened in 1914, as a memorial of Canon Barnett, the founder of Toynbee Hall (died 1913), to be a centre of social studies.

Among recent university benefactors chief place is taken by Mr. Walter Morrison, who in 1920 crowned his previous gifts (of £20,000 at least) by one of £50,000 to the Bodleian. Biological science in Oxford profited to an almost equal amount by the Welch bequest in 1915, while the study of modern languages has been encouraged by the foundation of the Zaharoff professorship of French and the Serena professorship of Italian.

The part of Oxford in the World War is best sketched in Craig's *Roll of Service*, with preface by Sir W. Raleigh (University Press, 1920); perhaps the most interesting short account of the changes in Oxford during the war period may be found in the *Oxford Magazine* for Dec. 8 1916. (J. WE.*)

**OYAMA, IWAO,** PRINCE (1842–1916), Japanese field-marshal (*see* 20.424). In 1914 he was nominated Lord Keeper of the Privy Seal, and in this capacity he attended the accession ceremony of the Emperor Yoshihito, which took place in Kyoto in Nov. 1915. In Dec. of the following year the Prince died, being accorded a State funeral by the imperial court. In him Japan lost one of her "Elder Statesmen."

[1] This estimate includes men training for the Air Force.
